Palmer's S. E., 1901, Table 59, May 3—June 28.

Q. Have you prepared two charts based upon the tables
12166 just read in evidence?

A. I have prepared two charts of the tables just read in evidence, 1 to 24, inclusive.

Q. Will you produce the charts and make them a part of your testimony?

A. I will. The two charts with the caption "Mean results Illinois River, Chemical Table, Jordan, Long and Palmer, months of May, June, July and August of years noted. L. P. Kinnicutt," are as follows:

MEAN RESULTS.

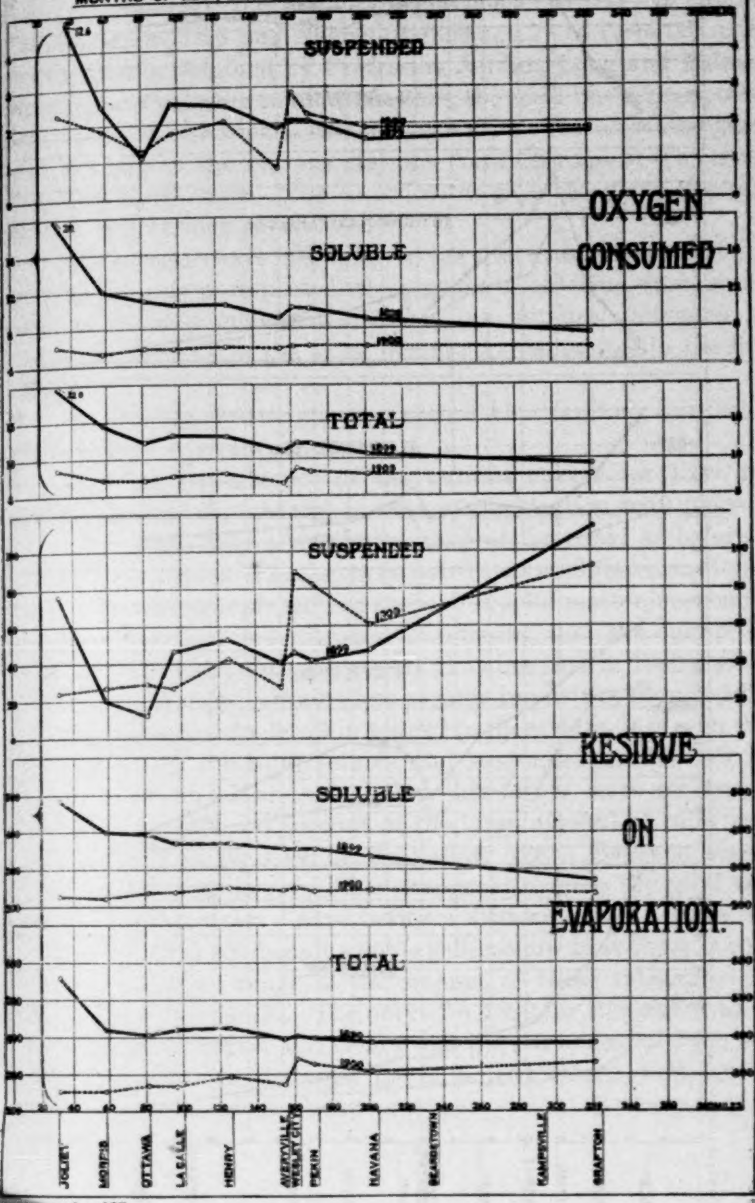
ILLINOIS RIVER

CHEMICAL TABLE.

JORDAN, LONG & PALMER.

L.P. KINNICUTT

MONTHS OF MAY, JUNE, JULY AND AUGUST OF YEARS NOTED.



MEAN RESULTS.

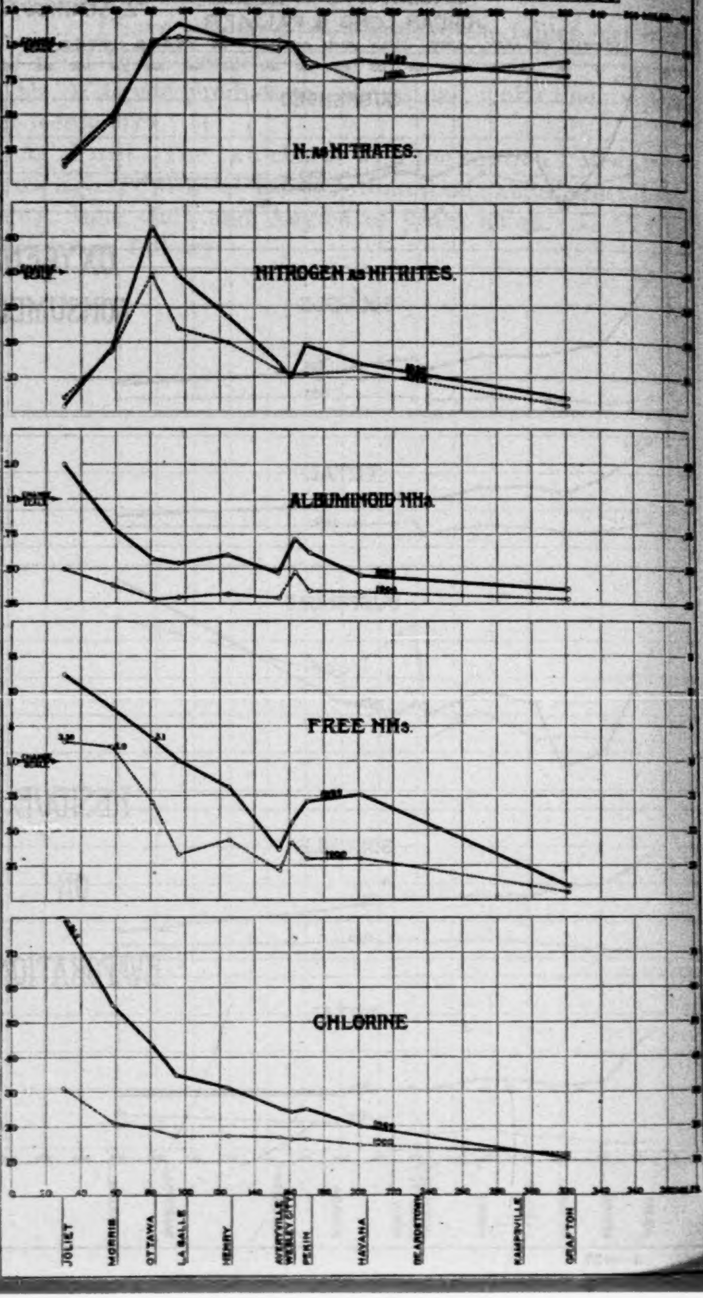
——ILLINOIS RIVER——

CHEMICAL TABLE.

JORDAN, LONG & PALMER.

L.P. KINNICUTT

MONTHS OF MAY, JUNE, JULY AND AUGUST OF YEARS NOTED.



Q. Will you explain the construction of these two charts 12169 just introduced, and what they show?

A. The first chart gives the curve representing the amount of the total solids, suspended solids, soluble solids; the total oxygen consumed; the soluble oxygen consumed for the months of May, June, July and August of 1899 and 1900, from the mean of the results obtained by Professors Jordan, Long and Palmer, for the months in the two stated years, the solid line representing the year 1899, the broken line the year 1900. The abscissae gives the distance of the various stations from Chicago at which the analyses were made. The co-ordinates give the parts per million of the various substances.

The second chart is similar to the first one, except that the curves there given represent the amount of chlorine, free ammonia, albuminoid ammonia, nitrogen as nitrites, nitrogen as nitrates, obtained in the same manner as the curves in the first chart.

Q. Taking the two charts together what sanitary conclusion do you draw from them?

A. The resemblance of the various curves for 1899 and 1900 show that the general process of purification took place in the same way after the opening of the canal as before it 12170 was opened. It is also to be noted that with the exception of the curves representing suspended solid matter, suspended oxygen consumed and nitrogen as nitrates, that the curves for 1900 are below the curves for 1899, showing that in 1900 a given volume of the river contains less organic impurities than in 1899.

To go more into detail in regard to these data, it is seen that the curves for the total soluble and suspended matter fall between Joliet and Morris, and that this fall is more marked in 1899 than in 1900, on account of the large amount of solid matter contained in the river in the former year. Between Morris and Ottawa there is very little change as regards the solid substances in the river. Also between Ottawa and La Salle the curves for total solids and soluble solids show that there is comparatively little change in the amount of these substances between these two places. The curve for 1899 for suspended solids rises between Ottawa and Henry and the curve for 1900 for suspended solids rises between La Salle and Henry, both curves falling again between Henry and Averyville. Between Averyville and Wesley City the curves in both years show an increase in the solid matter in the river. It is shown from the 12171 curve representing albuminoid ammonia to be of an animal and vegetable character.

From Pekin to Grafton the curves show very little increase or decrease in total substances in the river, but the curves for solid substances while showing little change for 1900 shows a slight decrease in 1899. In both years the curves show an increase in the suspended matter in the lower stages of the river, but that this matter is mineral rather than organic is shown by the curve representing oxygen consumed, which runs almost a straight line from Havana to Grafton. The curve representing oxygen consumed shows a large amount of organic matter at Joliet which they show is removed to great extent in both years before the river reaches Morris.

Between Averyville and Pekin the rapid rise in these curves shows an increase in organic matter between these points, and the decrease in the curves between Pekin and Grafton shows a removal of organic matter taking place in exactly the same way in both years.

The curves represeting the free and albuminoid ammonia show a very large amount of organic matter in both years at Joliet, a sharp decrease to Ottawa and then a gradual decrease to Averyville.

The curves, especially the curve representing the albuminoid ammonia rises slightly between Averyville and Pekin, showing the effect of a pollution at Peoria, and then both gradu-12172 ally falling until Grafton is reached, where the minimum amount of both free and albuminoid ammonia is shown by the curves to be present.

The nitrogen curves, especially the nitrogen as nitrites, show that the zone of greatest decomposition in the upper stages of the river, in both years, is in the neighborhood of Ottawa, and that the added volume due to the opening of the sanitary canal has not pushed this zone of decomposition further down the river. Beyond Averyville the rapid rise in the curve for free albuminoid ammonia, nitrogen as nitrites, and the decrease in the curve for nitrates, show the addition of polluted waters in both years at Peoria. This, as shown by the curves is more marked in 1899 than in 1900. The effect of this pollution is shown by the curves to extend to some degree to Havana, but at Grafton, the only curve to show that the water has been polluted at Peoria, is the nitrogen as nitrates.

The curves also show that a given volume of the river water contained less organic nitrogenous matter in 1900 than in 1899.

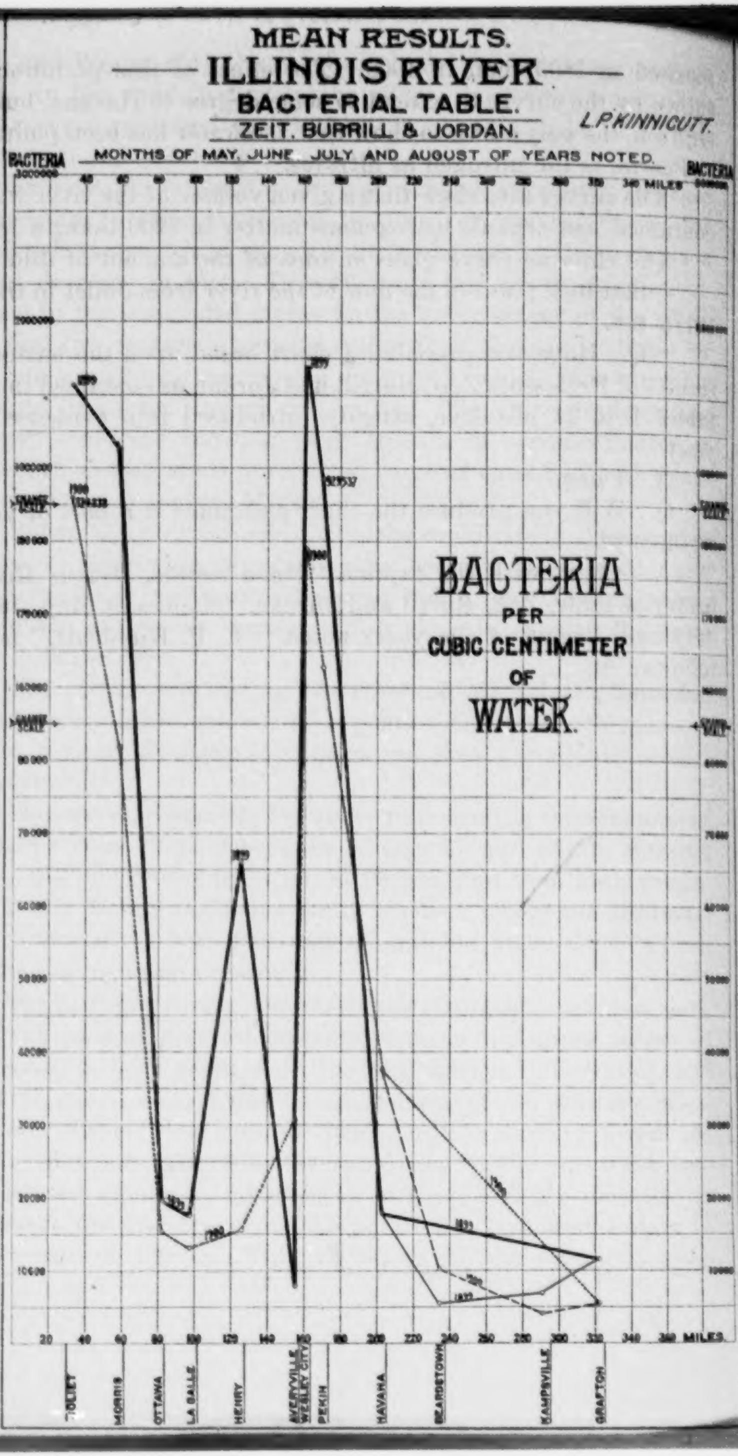
The chlorine curve gives an idea of the amount of dilution that took place in the flow of the river from Joliet to Grafton. 12173

Q. Have you prepared a chart based upon the bacterial results of Professors Zeit, Burrill and Jordan as contained in the tables 1 to 24 inclusive, already introduced into evidence by you?

A. I have

Q. Will you produce the chart and make it a part of your testimony?

A. Chart with the caption "Mean results, Illinois River, bacterial table, Zeit, Burril and Jordan. Months of May, June, July and August of the years noted. L. P. Kinnicutt," is as follows:



MEAN RESULTS.

ILLINOIS RIVER

BACTERIAL TABLE.

ZEIT, BURRILL & JORDAN.

L.P. KINNICUTT.

MONTHS OF MAY, JUNE JULY AND AUGUST OF YEARS NOTED.

BACTERIA PER CUBIC CENTIMETER OF WATER.

Q. Will you state what the chart just introduced in evi-
12175 dence shows?

A. The chart shows the bacterial contents of the river between Joliet and Grafton as obtained from results of Burrill, Jordan and Zeit, for the months of May, June, July and August, 1899 and 1900. The light lines between Havanna and Grafton represent only the months of May, and June, being the mean of Burrill and Jordan's results for May and June, Zeit making no determinations at these points. Consequently it is impossible to obtain a curve at these points representing the four months.

Q. Will you state what sanitary conclusions you draw from the chart just introduced in evidence?

A. Both curves show a great number of bacteria per cc. at Joliet. They then show a great decrease between Joliet and La Salle, a distance of 65 miles. The curves for 1899 show that between La Salle and Henry the number of bacteria increase rapidly, owing principally to the sewage of La Salle and Peru, but decrease almost as rapidly between Henry and Averyville.

The curve for 1900 shows also a slight increase from bac-
teria between La Salle and Henry and also a further in-
12176 crease between Henry and Averyville, due probably to
some local cause. Between Averyville and Wesley City the two show an increase of bacteria in both years, greater, however, between Wesley City and Pekin, in 1899 than in 1900. In both years the curves show a very great decrease between Wesley City and Havana, a distance of 40 miles, and the decrease continued though not so rapidly between Havana and Beardstown.

The curve for 1900 shows this decrease continues to Kampsville, while the curve for 1900 shows a rise between Beardstown and Kampsville. In both years they show an increased number between Kampsville and Grafton. The curve shows only three places in the river where the bacteria was greater in 1900 than in 1899, namely, at Averyville, Havana and Beardstown. The number of bacteria at Grafton is shown to be about 6,000 less per cc. in 1900 than in 1899.

Q. Have you prepared tables based upon the analytical data of Professors Jordan and Palmer on the tributaries of the Illinois River at their mouth, with the Illinois River at Grafton, for the months of May and June, 1899 and 1900, inclusive?

12177 A. I have.

Q. Will you produce and read the tables which you have prepared?

A. These tables are numbered from 25 to 40, inclusive, and are as follows:

12178 TABLE 25.—TRIBUTARIES TO THE ILLINOIS RIVER.

Desplaines River.—Lockport, 1899.

Mean of Jordan's and Palmer's results for May and June.

	Parts per million.
Total Solids	383.0

Palmer's S. E. 1901, Table 62, May 3—June 26.

Q. How were these tables prepared?

12194 A. These were prepared in the same manner as the other tables.

Q. Have you prepared a chart based upon the tables just read in evidence?

A. I have.

Q. Will you produce and read the chart which you have prepared?

A. The chart with the caption "Mean results, comparison of the sanitary character of the tributaries of the Illinois River at their mouths, with the Illinois River at Grafton, Jordan and Palmer, months of May and June, 1899 and 1900, L. P. Kinnicutt," is as follows:

MEAN RESULTS.

COMPARISON OF THE SANITARY CHARACTER
OF THE TRIBUTARIES OF THE

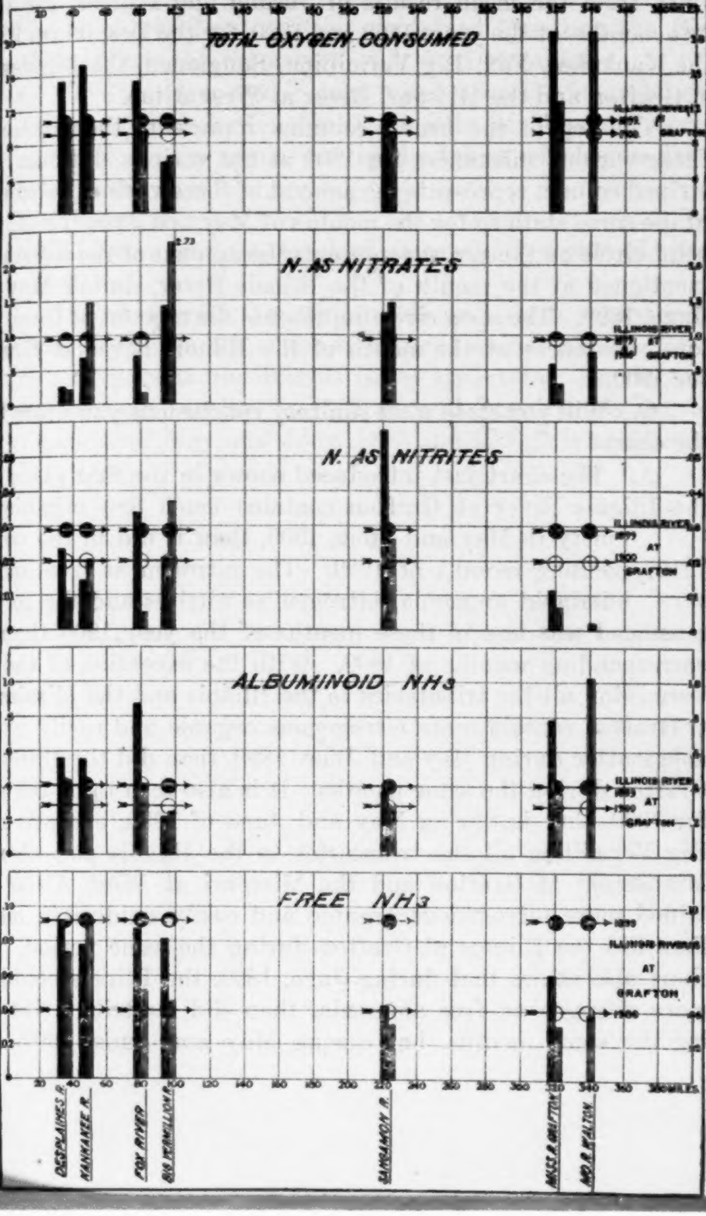
ILLINOIS RIVER

AT THEIR MOUTHS WITH THE ILLINOIS RIVER
AT

GRAFTON.

JORDAN AND PALMER.
MONTHS OF MAY AND JUNE, 1899 AND 1900.

L.P. KINNICUTT.



Q. State how this chart was constructed and what it
12196 shows?

A. In this chart is given the amount of free ammonia, albuminoid ammonia, nitrogen as nitrites, nitrogen as nitrates, oxygen consumed, for the months of May and June, 1899 and 1900, from the mean results of Jordan and Palmer, for these two months, of the years 1899 and 1900, for the Desplaines River, the Kankakee, Fox, Big Vermillion, Sangamon, the Mississippi at Grafton and the Missouri River at West Alton.

The top of the heavy columns represents the amount of these various substances for 1900 at the various stations. The striped column represents the amount of these various substances at the same stations for the months of May and June, 1900. The solid circle on the arrow represents the amount of the substances mentioned at the mouth of the Illinois River, during May and June, 1899. The open circle represents the amount of these various substances at the mouth of the Illinois River at Grafton for 1900.

Q. Will you state what sanitary conclusions you draw from the chart?

A. The chart just introduced shows in the first place that the Illinois River at Grafton contains much less organic impurity in May and June, 1900, than it did in the corres-
12197 ponding months of 1899. The nitrogen as free and albuminoid ammonia, nitrogen as nitrites and the oxygen consumed was less in these months of the year 1900 than the corresponding months of 1899. With the exception of the Big Vermillion all the tributaries to the Illinois and the Mississippi at Grafton contain more nitrogenous organic and easily oxidizable matter during May and June, 1899, than did the Illinois at Grafton during the same months. It is also seen to be the same for 1900, that is during May and June of 1900, excepting the Big Vermillion all the tributaries to the Illinois and also the Mississippi at Grafton and the Missouri at West Alton contained more nitrogenous organic and easily oxidizable matter than did the Illinois at Grafton during the same period. The chart also shows that during June, 1899, the Illinois contained more nitrogen as free ammonia, than did its tributaries during the same months, but during May and June, 1900, it is

seen that it contains less than the Desplaines, the Kankakee, the Fox and the Big Vermillion and practically the same amount as the Missouri.

In May and June, 1899, the Illinois contained more nitrogen as nitrites than any of its tributaries excepting the Fox and the Sangamon.

12198 In May and June, 1900, it contained less than the Big Vermillion, the Sangamon and the Desplaines.

Q. Have you prepared a chart based upon the bacterial results of Burrill and Jordan for the months of May and June, 1899 and 1900, which results are in the tables which you have just introduced?

A. I have.

Q. Will you produce the chart and make it a part of your testimony?

A. The chart with the caption "Mean results, comparison of the sanitary character of the tributaries of the Illinois River at their mouths with the Illinois River at Grafton, Burrill and Jordan's bacterial tables, L. P. Kinnicutt bacteria per cc. of water, months of May and June, 1899 and 1900," is as folows:

12199

MEAN RESULTS.

COMPARISON OF THE SANITARY CHARACTER
OF THE TRIBUTARIES OF THE

ILLINOIS RIVER

AT THEIR MOUTHS WITH THE ILLINOIS RIVER
AT

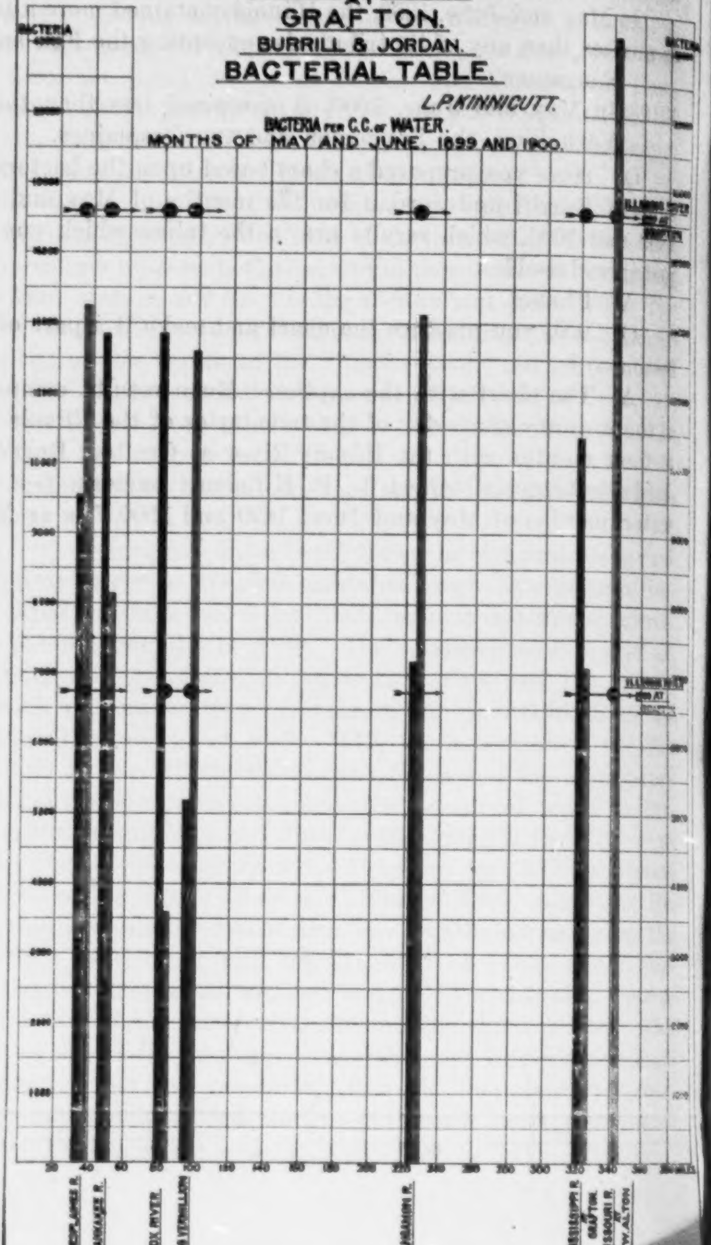
GRAFTON.

BURRILL & JORDAN.

BACTERIAL TABLE.

L. P. KINNICUTT.

BACTERIA PER C.C. OF WATER.
MONTHS OF MAY AND JUNE, 1899 AND 1900.



Q. Will you state how this chart is constructed and what 12200 it shows?

A. This chart is constructed similar to the last chart the four columns representing the number of bacteria per cc. at the mouths of the various rivers whose names are given at the bottom of the chart.

The solid ball and arrow at the top of the chart give the number of bacteria per cc. during the months of May and June, 1899, at Grafton, at the mouth of the Illinois River. The open ball and arrow in the middle of the chart represent the number of bacteria per cc. during May and June, 1900, on the Illinois River at Grafton.

Q. Will you state what sanitary conclusions you draw from the chart just introduced in evidence?

A. This chart shows that the Illinois River at Grafton during the months of May and June, 1899, contained over 10,000 more bacteria per cc. than during the same months of 1900. It also shows that the Illinois River at Grafton, during the months of May and June, 1899, contained more bacteria per cc. than did any of its tributaries, and more than the Mississippi at its mouth, during the same months.

During May and June of 1900 the Illinois River at Grafton contained, excluding the Fox River, not only less bac- 12201 teria per cc. than any of its trbutaries, less than the Mississippi at Grafton and the Missouri at West Alton, during the same months in 1900, but also contained a less number of bacteria than did any of its tributaries with one exception, the Big Vermillion, during the corresponding months of 1899. The Missouri at West Alton is shown by the chart to contain over 40,000 more bacteria per cc. during May and June, 1900, than the Illinois at Grafton. The Illinois at Grafton containing only 8,740 per cc.

There were no data from which the number of bacteria contained in the Missouri at West Alton in May and June, 1899, could be determined. The Missouri at West Alton during the months of May and June, 1900, was from bacterial representations, much more polluted than the Illinois at Grafton.

Q. Professor, in preparing these charts and tables why did you take the mean?

A. The reason that I took the mean was because it is my opinion that in taking a mean of the analytical data obtained by the various observers at the various stations on the Illinois River more accurate information can be obtained of the changes that take place in the river than by studying the data of any one person.

12202 Further, I did this because it is a method commonly employed in all scientific investigations, as for instance what are now considered as the figures representing the correct amount of hydrogen and oxygen in water were obtained not from the results of a single observer but by combining the data of many different experiments made by many different observers.

LEONARD P. KINNICUTT.

ADJOURNED until 10:00 a. m., Wednesday, March 16, 1904.

12203 10:00 a. m., Wednesday, March 16, 1904. Continuation pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

L. P. KINNICUTT

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

Q. Professor, will you state the steps of purification of Chicago sewage as the same passes out of the sewers of Chicago into the Chicago river, thence into the drainage canal and from thence to the Desplaines and Illinois rivers as you have shown by the tables and charts which you have offered in evidence in this case?

A. The sewage of Chicago as it enters from the sewers into the drainage canal undoubtedly contains a small amount of oxygen and the first action that takes place is undoubtedly anaerobic action in which part of such substances like urea are decomposed, ammonia being given off. The action in the sanitary canal is an anaerobic action, or very similar to that which takes place in the septic tank. By this action about 20 per
12204 cent. of the organic matter, as measured both by the loss in the albuminoid ammonia and by the loss in oxy-

gen consumed is removed from the sewage. Also a certain amount of suspended matter is removed and a certain amount of suspended matter has been rendered soluble and a certain amount has been converted into gases and into simpler products.

By this action the sewage is not only purified, but changed so that further purification will take place more easily. The next stage in the purification is the aerobic stage. Undoubtedly in the upper stretches of the river near Joliet we have both aerobic and anaerobic action taking place. Further down as at Ottawa we have principally an aerobic or nitrifying action. At about this point both in 1899 and 1900 is the zone of greatest decomposition. From this point the action, in my opinion, is entirely anaerobic or nitrifying action continued purification going on until we come to Averyville.

Between Averyville and Wesley City the tables and diagrams that I have made show that a large amount of organic polluted matter is added to the river. At Pekin or between Peoria and Pekin, we have also again more or less anaerobic action with aerobic action taking place.

The purification continues and between Pekin and Havana the action that takes place is aerobic or a nitrifying
12205 action. The aerobic purification then goes on until at Grafton, all the original organic matter which was in the sewage at Pekin has been decomposed and changed.

Q. From a careful consideration of all the tables and charts introduced into evidence by you, and consideration of it as a whole, what conclusions do you draw as to the effects of emptying the sewage of Chicago into the drainage canal and from thence into the Desplaines river and the Illinois river as to the effects of said sewage upon the waters of the Illinois river?

A. The effect of emptying the sewage of Chicago into the drainage canal into the Desplaines river at Joliet and then into the Illinois river is to increase the amount of organic matter in the upper stretches of the river.

The effect, however, of adding this organic matter to the upper stretches of the river is not noticed at Averyville except in the increased nitrogen contents of the river and the high chlorine and the same can be said at Grafton, at the mouth of the Illinois river. At that point the effect of the addition of the sewage to the Illinois river is seen only in the high chlorine and

the nitrogen as nitrates. This nitrogen content of the river is very different from the nitrogen content of the river at
12206 or above Ottawa. It is nitrogen which has been changed over and over again from the original character in which it occurred at Joliet. How this change takes place I have tried to show in my description of the nitrogen cycle.

Q. Are conditions worse or better in the Illinois river since the drainage canal was opened, carrying the sewage from Chicago into the Illinois river, than they were prior thereto, when the Chicago sewage was pumped into the Illinois river by way of the Illinois and Michigan canal?

A. I think the chart representing the Illinois river, May, June, July and August, 1899 and 1900, which was produced in evidence yesterday, shows clearly the conditions in the Illinois river in comparable months in 1899 and 1900. This chart compared the state of the river in corresponding periods in 1899 and 1900 and showed that the purification took place almost exactly in the same way during those two periods. Great amount of decomposition of organic matter between Joliet and Ottawa, the zone of greatest decomposition being in both years in the neighborhood of Ottawa. That purification in both years took place in a very similar way, is shown by the close corre-
12207 spondence of the various curves for the two periods. The rapid rise in free ammonia, albuminoid ammonia and nitrogen as nitrites between Averyville and Wesley City showed in both periods, the pollution entering the river between these points. The curves then show a repetition of what took place between Joliet and Averyville, the re-purification of the river. All the data as given by the two charts showed that the purification of the river in the two years took place exactly in the same way and also that the river at all points was purer during May, June, July and August in 1900 than in 1899.

Q. From all the analytical data which you have studied in this case, as well as your tables and charts offered in evidence, what are your conclusions as to whether or not the Illinois river purifies itself of sewage of Chicago before Grafton is reached?

A. My opinion is, as has been shown by my answers to the previous questions, that I believe that the sewage of Chicago is entirely decomposed before Grafton is reached, and that the only effect that we perceive in the river at Grafton is the nitrogen contents and in high chlorine.

12208 Q. Are the nitrogen contents and the chlorine such as are found in the river at Grafton of themselves elements dangerous to public health?

A. Not in the slightest degree. The chlorine and nitrogen content as found in the river at Grafton, have, as far as we know, absolutely no effect upon the human system.

Q. Have you studied the coli determinations made by Professor Jordan as the same appear in Streams Examinations, as well as his 1901 determinations, made at the laboratories at Peoria, Grafton and St. Louis, which tables have been introduced in evidence in this case?

A. I have studied the coli determinations as given by Professor Jordan in Streams Examinations, also his coli determinations made in 1901, and introduced in evidence in this case.

Q. Have you acquainted yourself with the experiments made upon the viability of the typhoid germ by Professor Jordan, Professor Zeit and Professor Russell?

A. I have.

Q. Taking into consideration all knowledge, chemical and bacterial, which you have, together with your personal knowledge of the conditions that obtain upon the water course, from Chicago to St. Louis, what is your opinion as to whether or not the deleterious and infectious properties of the sewage of
12209 Chicago, entering the drainage canal reach as far down the Illinois river as the town of Grafton?

A. Taking into consideration all the data that I have presented and all the data that I have studied regarding the Illinois river, and assuming that you mean by deleterious matters any matters that were in the sewage of Chicago that were deleterious to human health, and by infectious matter that you mean typhoid bacilli, I do not believe that they reach down the Illinois river as far as Grafton.

Q. Please give your reasons in full for your answer?

A. My reasons in full for this answer are that in my opinion all of the deleterious substances which may have been considered to have been contained in the Chicago sewage meaning by deleterious substances not bacterial life, have been entirely decomposed and rendered absolutely harmless long before the river reaches Grafton, and that the infected matter, meaning by that typhoid bacilli, which enters into the drainage canal from the sewage of Chicago would not survive the passage from Chicago to Grafton.

Q. State your opinion as an expert on water supplies
12210 for cities and towns as to whether or not the waters of the Mississippi river west of the center of the main channel of said river below the mouth of the Illinois river and down to the intake tower of the St. Louis water works at the chain of rocks is less valuable for drinking purposes and more liable to carry water-borne diseases, such as typhoid fever and cholera, now than it was before the sewage from the sanitary district of Chicago was run into the drainage canal and through it into the Illinois river?

A. All of the data that I have presented show that the Illinois river at Grafton does not contain undecomposed matter derived from the sewage of Chicago and it is my opinion that the typhoid bacilli from Chicago would not survive the journey from Chicago to Grafton, and therefore it is my opinion that the water of the Mississippi river west of the center of the main channel of said river below the mouth of the Illinois river and down to the intake tower of the St. Louis water works at the chain of rocks, is not less valuable for drinking purposes and not more liable to carry water-borne diseases, such as typhoid fever and cholera, now than it was before the sewage from the sani-
12211 tary district of Chicago was run into the drainage canal.

Q. If an increased volume of water in the Illinois river by the addition of the water of the drainage canal would make an increased speed in the current of the Illinois river would that increase in said current have any effect in increasing or diminishing the typhoid and liability to typhoid and other water-borne diseases on the part of the inhabitants of the State of Missouri using the water of the Mississippi river for drinking purposes below the mouth of the Illinois river?

A. I do not believe that any increased speed of the current of the Illinois river that would be caused by the addition of the water of the drainage canal would have any effect in increasing or diminishing the typhoid and liability to typhoid and other water-borne diseases on the part of the inhabitants of the State of Missouri using the waters of the Mississippi river for drinking purposes below the mouth of the Illinois river, and my opinion is based upon the character of the Illinois river.

Q. Professor Sedgwick, in answer to the question "What do you say as to the longevity of the germ of typhoid
12212 fever as a general proposition in connection with sewage polluted water" stated among other things, "My reason is that in a sewage polluted stream the typhoid germ might live in gradually diminishing numbers for weeks or months or even years." What is your opinion as to the correctness of that belief, based upon your knowledge as a sanitarian, and whether or not a typhoid fever germ might live in a sewage polluted stream for weeks, months or even years?

A. My opinion is that the typhoid fever could not live for weeks or months or even years in gradually diminishing numbers under such conditions, for all the experiments with which I am familiar show that the typhoid germ will live a less time in a polluted water than in a pure water.

Q. Professor Sedgwick, in answer to the following question: "Assuming that the germs of typhoid fever coming from the sewers of Chicago and passing by way of the drainage canal to Lake Peoria, be, in large numbers, deposited in the bed of Lake Peoria for the period of a month say, do you consider that typhoid germs would be entirely destroyed at the end of that time in that deposit," answered, "No sir." What do you say as to the assumption that typhoid germs could pass from the sewers of Chicago, by way of the drainage canal, to Lake Peoria, and be deposited there in the bed of Lake Peoria for a
12213 period of a month and as to whether or not typhoid germs coming from the drainage canal, under conditions as they exist today, would live for a period of a month and not be destroyed before the end of that period?

A. From the experiments that have been made I do not believe that the typhoid bacilli would live until it entered the slack waters at Peoria, and even assuming that it would survive the passage from Chicago to Peoria, and be deposited in the bed of Lake Peoria for a period of a month, I do not believe that it would live for a period of a month in such a deposit, and in this connection I would like to call attention to the experiments made by the Massachusetts State Board of Health, which are reported in the 34th Annual Report of the Massachusetts State Board of

Health in which the experiments of Mr. H. W. Clark and Stephen DeM. Gage are given.

In this experiment they show that when coli bacilli were placed in a storage reservoir once polluted but allowed to stand stagnant without further pollution, that the number of coli bacilli rapidly decreased and after 11 days bacilli coli were found in only one sample, this being collected near the bottom of the tank.

12214 On the 12th day and afterwards no B. coli were found in the water of any portion of the tank, and on emptying the tank on the 15th day the analyses from the scrapings of the bottom of the tank showed complete absence of this organism, showing it did not exist in the mud more than a day or two longer than it did in the water itself.

I would also like to cite in this connection an article on the investigation of the River Severn in the Shrewsbury District of England, given in the Second Report of the Royal Commission on Sewage Disposal appointed in 1898 to inquire and report what conditions of treatment and disposal of sewage may properly be adopted, in which report are given the analyses made of the mud of that river which show that the analysis of the mud 18 miles below where the sewage of Shrewsbury enters the river contained no more coli than the mud taken near the water works intake which is above where the sewage enters the river.

MR. CORUM: Complainant moves that the answer of the witness in reference to what the health reports of the State of Massachusetts show, and in reference to the table showing the bacterial examination of the River Severn be stricken from the evidence on the ground that his evidence is purely hearsay.

12215 Q. Professor Sedgwick, in answer to the question: "Assuming that typhoid fever germs coming from the Chicago sewers and deposited in large numbers in the lakes and slack water portions of the Illinois river above Peoria, do you or do you not consider that flood conditions, such as would scour the deposits from the beds of the streams would cause the water leaving Lake Peoria to contain at times more infectious and dangerous pollution than are at present in the diluted sewage entering at the Bear Trap Dam at the foot of the drainage canal?" stated: "I think at times it might." What is your opinion taking into consideration all that you know about the conditions in the drainage canal, the Desplaines and the Illinois rivers as a bacteriologist, chemist and sanitary expert as to whether such a condition at times might exist?

A. From all the data that I possess and from all the knowledge that I have acquired regarding the life of the typhoid bacilli, I do not think it is possible that the waters leaving Lake Peoria would contain at times more infectious and dangerous pollution than is at present in the polluted sewage entering at the Bear Trap Dam at the foot of the drainage canal.

Q. What is your opinion, based upon all the knowledge 12216 which you have of conditions at Lake Peoria, as a chemist and sanitary expert and a bacteriologist, as to whether at any time, under any conditions, the number of typhoid fever germs at any point is even as great as they are at the Bear Trap Dam at the end of the drainage canal?

A. I am very firmly of the opinion that the waters of Lake Peoria can not at any time contain as much infectious and dangerous material, as the waters at Bear Trap Dam, and I know absolutely of no data that would warrant any such assumption.

Q. Do you know of any evidence scientifically secured or otherwise that shows that accumulations of typhoid germs are found in the lakes or slack water basins of rivers and remain there in storage in vast numbers for any considerable period of time in a virulent state and finally flushed out by freshets so that the number of typhoid fever germs are carried by the stream a considerable distance from the source of pollution in greater quantities than they exist at the source of pollution?

A. I know of no evidence scientifically secured or otherwise that would show such a condition of affairs.

Q. Now, assuming that the only pollution of the river was that contributed to it by the Chicago Sanitary District, and having in mind a large amount of typhoid fever existing in said district, do you or do you not consider the effect of the time interval, dilution and sedimentation occurring between Chicago and Grafton would be such as to render the water as it 12217 reaches the Mississippi river at all times free from producing water-borne diseases in those who drink it?

A. Knowing the character of the Illinois river and bearing in mind the amount of sedimentation, the amount of dilution and the amount of purification that occurs between Chicago and

Grafton, and especially bearing in mind the time element, I do believe that the time interval would render the Mississippi river water at all times free from liability of producing water-borne diseases from pathogenic bacteria entering the Illinois river by way of the drainage canal.

Q. Is there anything based upon your knowledge as a chemist, bacteriologist and sanitary expert, which you know that would lead you to believe that the water coming from the Illinois river was infected from the sewage of Chicago, and assume that the water from the Illinois river mixed with the water from the Mississippi river at Grafton and subsequently mixed with the waters of the Missouri river at its mouth, do you consider the waters of the Illinois river thus commingled with the waters of the Mississippi and Missouri rivers a menace to the health of the inhabitants of Missouri living on the Missouri shore, 12218 using the Mississippi river water for drinking purposes, and those below on the Missouri shore?

A. From all the knowledge that I possess as a sanitary expert, I do not believe that the water of the Illinois river at Grafton is infected from the sewage of Chicago, meaning by infection typhoid bacilli which came into the Illinois river from the Chicago sewage, and this being my opinoin I do not consider that the water from the Illinois river mixed with the water of the Mississippi river at Grafton and subsequently mixed with the waters of the Missouri river at its mouth, thus commingling with the waters of the Missisippi and Missouri rivers is a menace to the health of the inhabitants living upon the Mississippi river, using the Mississippi river water for drinking purposes at points on the Missouri shore.

Q. Assuming that there was no typhoid fever pollution of the waters upon the water shed of the Mississippi river or its tributaries above the intake of the St. Louis water works, other than that derived from the sanitary district of Chicago, 12219 do you or do you not believe that typhoid fever germs from said district are liable to find their way into the water supply of the city of St. Louis through the intake at the chain of rocks?

A. It being my opinion that typhoid fever bacilli from Chicago entering the Illinois river do not survive the journey from Chicago to Grafton, and assuming that there were no typhoid fever pollutions of the waters upon the water shed of the Mississippi river or its tributaries, above the intake of the St. Louis water works, except that which came from Chicago, my opinion is, for the reasons stated above, that typhoid fever germs from said district are not liable to find their way into the water supply of the city of St. Louis through the intake tower at the chain of rocks.

Q. Professor Sedgwick, in answer to the question just propounded to you, answered: "I believe that they are liable to find their way into the intake," and when asked why, answered: "For the reason that typhoid fever having been frequently very abundant in the city of Chicago I must start with the assumption that a very large number of typhoid germs find their way into the sewage of the city, pass through the sewers and into the
drainage canal and subject to local conditions may in
12220 diminishing numbers pass through the Illinois river,
mingle with the waters of the Mississippi river, pass over
to the other side, and find their way into the intake at the chain of rocks." I want to ask you, do you know of any evidence based on your analyses, experiments or otherwise that justifies the assumption that typhoid fever germs will pass from Chicago, out into the drainage canal, through the Illinois river, into the Mississippi and thence to the chain of rocks and the intake tower of St. Louis?

A. I can find no evidence that shows that the typhoid bacilli does or can pass from Chicago out into the Illinois river, thence to the chain of rocks and the intake tower at St. Louis.

Q. Professor, do you consider that the Illinois river water containing mixed sewage and canal water from the Chicago drainage canal has rendered less safe and wholesome now than before the opening of the canal, the waters of the Mississippi for drinking purposes on the part of the inhabitants of the State of Missouri, the waters of the Mississippi river below the mouth of the Illinois?

A. From all the data that I have studied, and from all
12221 the knowledge that I have been able to obtain regarding
the Illinois river I find not the slightest evidence that
the Illinois river, containing the mixed sewage and canal water from the Chicago drainage district since the opening of the drainage canal renders the waters of the Mississippi river below

the mouth of the Illinois river less safe and wholesome than it was before the opening of the canal, for drinking purposes on the part of the inhabitants of Missouri.

Q. Professor Sedgwick, in answer to a question, among other things, said: "The mere presence of pollution, I mean by that uninfected sewage, that is supposing Chicago reduced her typhoid death rate and would still put her sewage down there, that sewage as favoring the longevity and growth of germs that get in from Peoria or elsewhere would be an added menace to the cities with water supply, even if she did not send typhoid fever germs down, sending the filth along is serious." I will ask you what is your opinion, based upon your experience as a chemist and bacteriologist and sanitarian as to whether the sewage from Chicago favors the longevity or growth of germs from Peoria or anywhere else, emptying their sewage in the
12222 Illinois river?

A. From various experiments that have been made it has been shown that the vitality of the typhoid bacilli is greater in pure water than in water polluted by sewage, and basing my opinion on these facts, it is my opinion that the sewage from Chicago does not favor the longevity or growth of germs from Peoria or anywhere else emptying their sewage into the Illinois river.

Q. State in detail what position the science of bacteriology occupies in regard to the ascertainment of the purity of river waters?

A. Bacteriology enables us to determine the number of bacteria in a water and to isolate and determine the number of certain species of bacteria. It enables us to tell indirectly something regarding the condition and amount of organic substances in a water and also to determine the vitality of certain species of bacteria. For studying the sanitary character of the water a knowledge of bacteriology is absolutely necessary.

Q. What position does chemistry occupy in what is known as sanitary science?

A. Chemistry tells us the amount of salts in the water, the amount and condition of the organic matter. It enables us to tell something regarding the past history of a water and in-
12223 directly gives us an idea as to the bacterial condition of the water. It also enables us to understand how the com-

plex organic compounds such as occur in the food products and nature when placed in water are broken up, decomposed and gradually changed into gas and mineral substances.

Q. In the ascertainment of the quality of the river water what aid are chemisty and bacteriology to the sanitarian in forming a judgment of the quality and potability of water?

A. It is absolutely necessary to employ both chemistry and bacteriology, and it is impossible to form a correct judgment as to the quality and the potability of a water without the aid of both of these sciences.

Q. Does not a sanitary expert call to his assistance all the information available from chemical and bacterial sciences as well as knowledge of the source of pollution in passing judgment upon the sanitary character of a river?

A. In passing judgment on the sanitary character of a river it is almost absolutely necessary to have a knowledge of the sources of pollution and a knowledge of the water shed. Without a knowledge of the nature of the water shed it is almost impossible to form a correct idea of chemistry and bacteriology alone, of the changes that are taking place in the river.

1224 Q. From the tables of analyses submitted in evidence by the chemists and bacteriologists who have testified in this case, whose tables you have examined, and from the tables and charts which you have introduced, where is the zone of greatest decomposition located in the Illinois river?

A. From all the tables that I have studied and the various analyses that have been made upon the waters of the Illinois river, all indicate that the zone of the greatest decomposition in both 1899 and 1900, before and after the sanitary canal was opened in the upper stretches of the river was in the neighborhood of Ottawa. In the lower stretches of the river there is in both years another zone of decompostion somewhere between Pekin and Havana.

Q. Will you differentiate between the zone of greatest decomposition and of greatest purification?

A. In my opinion the zone of greatest decomposition is shown principally by the nitrogen as nitrites. The zone of purification is shown by the change of the nitrites into nitrates, that being the last change which organic matters undergo, it being transformed into mineral substances. The zone of purification immediately follows the zone of greatest decomposition.

12225 Q. As a sanitary expert, availing yourself of all chemical and bacterial knowledge which is available to you, what is your opinion as to whether a typhoid bacillus lying in the sediment of a polluted stream for a period in excess of sixty days would be able to cause tphoid fever when taken into the human system after it had remained in such sediment for that length of time?

A. My opinion is that if it was possible for a typhoid bacillus to remain in the sediment of a polluted stream for a period in excess of sixty days the virulence of the typhoid bacillus would be so greatly diminished that when taken into the human system, in all human probability it would not be able to cause typhoid fever.

12226 Q. What is your opinion as a sanitary expert, as to whether pollution, or typhoid fever bacilli, coming from the sewage of Chicago through the drainage canal, and deposited on the bottom of the Desplaines and Illinois rivers, between Chicago and Peoria, can remain there for a period of from 30 to 60 days, and yet retain its dangerous qualities as well as its pathogenesis?

A. If by polluted matter you mean the organic matter that is contained in sewage, I believe that it could be deposited in the upper stretches of the Illinois river and remain there from 30 to 60 days. As regards infected matter, meaning especially typhoid bacilli, I do not believe that it could remain for a period of from 30 to 60 days and yet retain its dangerous qualities.

Q. From your personal knowledge of the Illinois river, and your knowledge as a sanitary expert, together with your chemical and bacterial knowledge derived from every source, what is your opinion as to whether sewage from the city of Chicago passing through the drainage canal into the Illinois river, at different seasons of the year and at different stages of

12227 the water, in the Illinois river, would be a danger and a menace to the inhabitants of Missouri and to the citizens of the city of St. Louis, using the water of the Mississippi river at the intake tower at the chain of rocks?

A. From my knowledge of the Illinois river, flowing as it does at high water over a very large amount of territory, and the fact that the river is studded with lakes, nearly all the way from Upper Peoria Lake to its mouth, I do not believe that even at the different stages of water of the Illinois river, the sewage from the city of Chicago, passing through the drainage canal into the Illinois, at different seasons of the year, would be a danger or a menace to the inhabitants of Missouri and the citizens of the city of St. Louis, using the water of the Mississippi river at the intake tower, at the chain of rocks.

Q. What is your opinion as a sanitary expert, based upon your examinations of the tables of analyses introduced in evidence by Professors Long, Palmer, Burrill and Jordan of the waters of the Illinois, Mississippi and Missouri rivers,
12228 as represented by such tables as you have examined, as to which one of those three rivers, from those analyses. discloses the least amount of impurity or pollution?

A. From the chemical and bacterial analyses introduced in evidence by Professors Long, Palmer, Burrill and Jordan, together with my study of the tables and charts that I have prepared and introduced as evidence, it is my opinion that the Mississippi and the Illinois rivers practically contain about the same amount of impurity, while the Missouri river contans a larger amount of impurity than either of the other two rivers named.

Q. If the Illinois river discloses from such data as aforesaid a less amount of impurity than the Missouri, what would be the effect of the waters of the Illinois river emptying into the Mississippi river at Grafton, and subsequently uniting
12229 with the Missouri river at its mouth, upon the combined waters of the Mississippi and the Missouri rivers at the intake at the chain of rocks?

A. The effect under the conditions stated would be one of purification upon the combined waters of the Mississippi and the Missouri rivers, and would render those waters less harmful.

Q. Does the mixing of the Illinois with the Mississippi and the Missouri rivers, as indicated in the foregong question, create any added danger, or pollute or contaminate the waters of the Missouri and the Mississippi rivers, at Peoria, or at Grafton?

A. It does not.

Q. From your knowledge of the conditions that obtain in and along the Illinois river, what is your opinion as a sanitary expert as to whether deleterious substances and infected matter, or pathogenic germs, which come through the drainage canal from the sewers of the city of Chicago, would reach as far down the Illinois river as the city of Grafton? 12230

A. It is my opinion as a sanitary expert, and with a knowledge of conditions that obtain in and along the Illinois river, and from the evidence that has been submitted in this case, that such infected matter or pathogenic germs which come into the drainage canal from Chicago, do not reach as far down the Illinois river as the city of Grafton.

Q. Would any of these substances in a dangerous stage from Chicago reach the intake tower at the St. Louis water works, at the chain of rocks, in your opinion?

A. If they would not reach as far down the Illinois river as the city of Grafton, it is impossible that any of these substances in a dangerous state would reach the intake tower of the St. Louis water works at the chain of rocks.

Q. As a sanitary expert do you consider the sewage of Chicago, entering the drainage canal, and the Illinois river, which in turn empties into the Mississippi river, a cause of danger to the inhabitants of the State of Missouri, and the citizens of the city of St. Louis, taking their water supply from the Mississippi river? 12231

A. For the reasons which I have already stated, which are based upon all the knowledge which I have been able to obtain, regarding the Illinois river, I do not consider that the sewage of Chicago, entering the drainage canal, and the Illinois river, which in turn empties into the Mississippi river, a menace and a danger to the inhabitants of the State of Missouri or to the citizens of the city of St. Louis, taking their water supply from the Mississippi river.

Q. What is your opinion as a sanitary expert as to whether the germs of typhoid fever could lie in the sediment of the drainage canal, upon the bottom of the Illinois river, for a period of from one to three years?

A. As stated in answer to a previous question, where I refer to experiments made by the Massachusetts State Board of

Health, it is my opinion that the germ of typhoid fever could not lie in the sediment of the drainage canal, or upon the bottom of the Illinois river, for a period of from one to three
12232 years.

Q. What is your opinion as to whether the typhoid bacillus deposited on the bottom of the Illinois river could remain there for a period of upwards of five years and then be stirred up by the action of the waves and wind, steamboats or any other means, and continue its journey down to St. Louis in a virulent state and be a cause of danger to the inhabitants of the State of Missouri and the citizens of the city of St. Louis, using the waters of the Mississippi river for domestic and drinking purposes?

A. Believing that it could not exist for three years in the mud of the Illinois river. I certainly do not believe it could exist for five years.

Q. What is your opinion as an expert chemist, as to the chemical tables brought in evidence by Professors Long, Palmer, Burrill and Jordan, of the waters of the Illinois river, as to whether the pollution and contamination from the sewers of Chicago, emptying into the Chicago river, thence into the drainage canal, could be manifested and present as far down the Illinois river as Grafton, and at the chain of rocks, on the Mississippi river?

12233 A. In my opinion, the only effect the pollution and contamination from the sewers of Chicago, entering into the Chicago river, thence into the drainage canal, that could be noticed at the chain of rocks on the Mississippi river, is a higher chlorine and nitrogen contents of the river.

Q. From your examination of the different tables, what is your opinion as an expert chemist as to to whether any of the original organic matter of the sewage from Chicago finds its way into the intake tower of the St. Louis water works, at the chain of rocks?

A. From a study of the analytic data, which has been submitted in evidence in this case, it is my opinion that all this analytical data shows that this organic matter of the sewage from Chicago has been decomposed before it reaches Grafton. Consequently, none of the organic matter from the sewage of

Chicago finds its way into the intake tower of the St. Louis water works at the chain of rocks.

Q. Will you state as a sanitary expert, basing your opinion upon all the information which you possess in this case, whether the water supply of St. Louis is contaminated
12234 and polluted or injured by the sewage of Chicago entering the drainage canal and thence into the Illinois river?

A. In my opinion it is not.

Q. What effect does the increased volume of water of the Illinois river have upon the lowlands lying along the banks of the Illinois river?

A. The effect of the increased volume of water in the Illinois river is to cover with water the low lands lying on the banks.

Q. If the increased water at flood times, from the tributaries of the Illinois river, as well as the Illinois river itself, exclusive of the waters from the drainage canal, causes a large area of land to be overflowed along the Illinois river flats, what effect does this over-flow have upon the contamination of the sewage from Chicago, entering the Illinois river through the said canal?

A. It is a well known fact that the larger amount of surface over which the water spreads, the greater will be
12235 the amount of deposition, consequently the increased water at flood times, causing a larger area of land to be overflowed along the Illinois river, would tend to cause a greater deposition of the suspended matter coming from the sewage of Chicago and entering the Illinois river through its canal.

Q. Will you state, as an expert sanitarian, from all sources of knowledge which you possess, whether the water of the Mississippi river at the chain of rocks, was prior to January, 1900, a safe and potable drinking water, fitted for domestic use and drinking purposes in its raw state.

A. From the examinations that have been made, and the finding of the coli bacilli in the majority of one cubic centimeter samples, I do not believe that the Mississippi river at the chain of rocks was prior to 1900 a safe and potable drinking water, fitted for domestic and drinking purposes in its raw state.

Q. Was the Missouri river water a safe water for drinking and domestic purposes, prior to opening of the drainage canal, in 1900?

12236 A. For the same reasons, this is my opinion that the Missouri river was not a safe water for domestic purposes prior to the opening of the drainage canal in 1900.

Q. Was the Illinois river a safe water for drinking and domestic purposes prior to the opening of the drainage canal in 1900?

A. In my opinion for the same reasons as stated above the Illinois was not a safe drinking water for domestic purposes prior to the opening of the drainage canal in 1900.

Q. Have the sanitary conditions of the water of the Illinois river at Grafton been improved or damaged by the opening of the drainage canal?

A. It is my opinion all the examinations that I have studied, as well as my own tables and charts show, that the waters of the Illinois river at Grafton are in a purer state since the opening of the drainage canal.

Q. Since the opening of the drainage canal are the waters of the Illinois river less sanitary than the waters of the Missouri and the Mississippi rivers?

A. They are certainly not less sanitary than the waters of the Mississippi river, and they are in a better sanitary condition, as shown by the bacterial and chemical analyses than the waters of the Missouri river. 12237

Q. What effect does the sewage discharged through the drainage canal have upon the Missouri and the Mississippi river waters at the chain of rocks?

A. The only effect in my opinion that the sewage discharged through the drainage canal has upon the Missouri or the Mississippi river waters at the chain of rocks, is in the increase in the amount of chlorine and also in the quantity of nitrogen contents, neither of which elements as far as known, has any effect upon the human system.

Q. Does the sewage of Chicago, in your opinion, ever reach the intake tower of the city of St. Louis, at the chain of rocks?

A. The sewage of chicago as sewage in my opinion never reaches the Mississippi river at the chain or rocks, at the intake tower.

Q. Is the water of the Mississippi and the Missouri rivers, exclusive of the water of the Illinois river, a safe and suitable drinking water for domestic purposes to be used by the citizens of Missouri in its raw state? 12238

A. I do not consider that either the waters of the Mississippi or the Missouri are a safe and suitable water for drinking by the citizens of Missouri.

Q. If the sewage of Peoria and all the other towns along the Illinois river and its tributaries were eliminated from the Illinois river, would all the original organic matter of the sewage of Chicago be eliminated before it reaches Grafton?

A. In my opinion, it would.

Q. Taking into consideration all the knowledge which you possess in regard to the chemical, bacterial and physical conditions of the water of the Illinois river and its tributaries, and the river itself, the different towns sewering into the Illinois river and its tributaries, the population upon the water shed of the Illinois river, both rural and urban, the stages of the river under all conditions, and during all the seasons of the year, what is your opinion, as a sanitarian, as to the effect of flowing the sewage of Chicago through the drainage canal, into 12239 the Desplaines and Illinois rivers, upon the inhabitants of the State of Missouri and the citizens of St. Louis, using the waters of the Mississippi river for drinking and domestic purposes?

A. It is my opinion that all of the organic matter contained in the sewage of Chicago has been entirely decomposed and changed before the river reaches Grafton, and it is also my opinion, based upon all the knowledge that I possess, that the infected matter, meaning by that, the typhoid bacilli, have not been able to survive the journey from Chicago to Grafton. Taking into consideration all the analytical data I have examined and studied, including the chemical and bacterial analyses made upon the waters of the Illinois river and its tributaries, and my own tables and charts, and at the same time taking into account certain towns sewering into the Illinois river and its tributaries, and taking also into account the rural and urban population upon this water shed, my opinion is that there is no evidence that the flowing of the sewage of Chicago from the drainage canal into the Desplaines river has any effect upon the

inhabitants of Missouri, using the waters of the Mis-
12240 sissippi river for drinking and domestic purposes.

LEONARD P. KINNICUTT.

Adjourned until 10:30 a. m., March 17th, A. D. 1904.

10:30 A. M., Thursday, March 17, 1904.

Present, the Commissioner and same counsel representing the respective parties.

Complainant not being ready to proceed with cross-examination of L. P. Kinnicutt an adjournment was taken until 2 p. m. of the same day.

2 P. M., Thursday, March 17, 1904.

Met pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

Complainant not being ready to proceed with cross-examination of counsel, by consent, an adjournment was taken until March 26, 1904, at 9 a. m., at the Stafford Hotel, Baltimore, Maryland.

THE STATE OF MISSOURI
12241 VS.
THE STATE OF ILLINOIS and
SANITARY DISTRICT OF CHICAGO.

Met pursuant to adjournment, Saturday, March 26, 1904, 9:00 A. M., at the Stafford Hotel, Baltimore, Md.

Present: Frank S. Bright, Esq., Commissioner United State Supreme Court, S. P. Jeffries, Esq., and James Todd, Esq. representing the respective parties.

WILLIAM S. THAYER

called as a witness in behalf of the defendants, State of Illinois and the Sanitary District of Chicago, being duly sworn by the Commissioner and upon examination in chief by Mr. Todd testified as follows:

Q. Please state your full name?

A. William S. Thayer.

Q. What is your business?

A. Physician.

12242 Q. Where do you reside?

A. 406 Cathedral Street, Baltimore.

Q. Where did you graduate, Doctor?

A. At Harvard University.

Q. When did you graduate at Harvard University?

A. In medicine, in 1899, in the academic department, A. B., 1885.

Q. After graduating in medicine what did you do?

A. I spent a year as house physician at the Massachusetts General Hospital. I should say that that year was the year 1888-1889. It was the rule that one accepting the position of house physician should not take his degree until the year following the date of his graduation so that my degree dates from 1889. After that I spent a year abroad in studying in Berlin and Vienna and in the fall of 1890 I came to Baltimore as assistant resident physician in the Johns Hopkins Hospital. In the fall of 1891 I was appointed resident physician in the fall of 1895 I was made associate in medicine at the Johns Hopkins University and in '96 or '97 associate professor of medicine, which I have 12243 been since then. I lived in the hospital as resident physician from 1891 to 1898.

Q. Have you pursued your study in Europe?

A. I studied in Paris for three months during the fall of 1893.

Q. What positions do you hold?

A. I am one of the physicians in chief of the Johns Hopkins Hospital Dispensary, associate in medicine at the Johns Hopkins Hospital, associate professor of medicine in the Johns Hopkins University and visiting physician to the Union Protestant Infirmary.

Q. What branch of medicine have you given particular attention to?

A. To internal medicine.

Q. Have you made a special study of the so-called germ diseases?

A. Yes sir, I have, in regard particularly to malarial fever and typhoid fever and in a general way to those infectious dis-

eases which come into the practice of a practitioner of
12244 general medicine; I have made a special study of malarial
fever and a number of phases of typhoid fever.

Q. Do the diseases caused by germs come within the scope of your study?

A. They do. At least I may perhaps say, most of them.

Q. Which diseases have you made a special study of, i. e., germ diseases?

A. Malarial fever and typhoid fever particularly.

Q. Have you made any study upon typhoid fever and malarial fever from the standpoint of a bacteriologist or clinician?

A. I have been studying them clinically, steadily, since the beginning of my practice, and I have made special investigations with regard to the parasites of malarial fever.

Q. In connection with such study as you have detailed, have you taken up the question of the proper diagnosis of fevers of the kinds known as typhoid and malarial?

12245 A. Yes, I have.

Q. Have you had any experience in the diagnosis of these fevers, either in the laboratory or at the bed side?

A. I have had continued experience both at the bed side—more particularly at the bed side and also in the laboratory for the last—since 1889—since the summer of 1888, really.

Q. What is the meaning of clinical diagnosis?

A. Clinical diagnosis is bedside diagnosis—at the bedside of the patient. It is bedside diagnosis in contradistinction to pathological or post mortem diagnosis.

Q. What is typhoid fever and its clinical diagnosis?

A. Typhoid fever is a disease due to the entrance into the organization of a specific bacterium, the typhoid bacillus. That organism enters into the body in all probability in the vast majority of cases through the gastro intestinal tract, passes into the general circulation and causes a septicaemia, in other words,
a general blood poisoning. It furthermore is associated
12246 with certain anatomical changes more particularly a
swelling of Peyers patches and the solitary follicles of the small intestine, enlargement of the retroperitoneal glands and an enlargement of the spleen, together with certain widespread degenerative changes in various organs throughout the body.

This results in a clinical picture, the more important features of which are due—not to the local changes, but to a poisoning produced by certain products of the growth of this bacillus. Those symptoms are in the first place a fever of usually rather gradual onset preceded often by a week or ten days or so of sensations of malaise and headache, not infrequently nose bleed, a gradually rising fever which reaches its height at the end of from several days to a week as a rule and lasts on an average of about three weeks falling gradually to noraml. It may last a short time and it may last a very much longer time. This fever is associated ususally with certain other symptoms which are
1227 of considerable importance, a generally dull apathetic condition of the patient, which is spoken of as the typhoid condition and which though it may be present in other intoxications, is rather particularly characteristic of this disease. The appearance of the eruption, which is present in the majority of cases, though not always; this appears usually about the end of the first or beginning of the second week, an eruption of small so-called "rose spots." Very often there is a slight bronchitis. A palpably enlarged spleen. There are not infrequently associated with these symptoms others which are due more particularly to the local lesions, such for instance as diarrhoea, the result in most cases of severe intestinal involvment, abdominal distention, or of other complications such as hemorrhage of the bowels due to ulcerations through a large vessel, or perforation of the intestine, which occurs in a small proportion of cases. Towards the end of the first week or by the tenth day as a rule there appears in the blood serum, a substance, which, when the serum is added to cultures of the typhoid bacillus, even
1248 though the serum be diluted to a high degree, produces a clumping and loss of motility of the bacilli—the phenomenon known as the Widal reaction. This reaction when positive, after proper precautions have been taken in the procedure, is specific of typhoid fever.

It is fair to say that it sometimes does not appear until very late and it is not impossible that there may be cases of typhoid fever though very rarely, in which it does not appear, but this is probably of the utmost rarity.

With regard to the diagnosis of typhoid fever I might say one word more. In contradistinction to what is true in fevers due to or associated with local inflammatory processes, the white corpuscles of the blood are diminished in number in typhoid fever while in all diseases due to local inflammatory process they are increased—sometimes an important diagnostic point.

But the diagnosis of typhoid fever depends upon a careful consideration of the whole situation. It is often impos-
12249 sible to make a positive diagnosis of typhoid fever before the end of the first week, but it is rarely the case that one is not able to recognize typhoid fever if the disease is carefully observed.

Q. Are all the symptoms which you have indicated in your answer always present in a case of typhoid fever?

A. No, there is not a single one of the symptoms of typhoid fever which might not be absent from a given case. While one can draw a good average picture, such as one reads in a text book of medicine, the individual who learns to recognize typhoid fever only from such a picture is bound to make many mistakes. The diagnosis can only be made by a careful consideration of all the different symptoms putting them together and drawing proper conclusions, and in cases which are not typical, proper diagnosis demands experience. There is no disease in which experience is more important than in typhoid fever.

Q. What experience have you had and what studies have you pursued with malarial fever?

12250 A. Shortly after coming to Baltimore in 1890—the fall of 1890, I began to devote myself especially to the study of the malarial fevers as here observed. After five years study—Dr. Hewetson and I published a report on the subject in the Johns Hopkins Hospital Reports in which we gave the results of our studies of the malarial fevers and the malarial parasites. I continued my work afterwards, working principally on malaria up to 1900 and during that time published a number of papers. I published a text book "Lectures on the Malarial Fevers" in 1897; in the spring of 1900, I delivered an address before the Congress of American Physicians and Surgeons on the recent progress in our knowledge concerning malarial fevers. I have, also, I may say, looked into the matter personally in other parts of this country having made trips to Memphis, to New

Orleans, to certain parts of Eastern North Carolina and Virginia, to look up special points.

Q. What is malarial fever and its clinical diagnosis?

A. Malarial fever or more properly the malarial fevers,
12251 for there are several distinct types, are due to the entrance into the blood of specific micro organisms. These belong to the lowest order of animal parasites. They enter into the red blood corpuscles of the infected individual and pursue their cycle of existence in the red corpuscles producing characteristic symptoms in the patient. Here as all over the world there are three types of malaria. Tertian fever, Quartan fever and what is called Aestivo-Autumnal or Tropical fever. The regular intermittent Tertian and Quartan fevers are characterized by chills or febral paroxysms occurring at regular intervals. In infections with the Tertian parasites they occur every other day, in infections with the Quartan parasite, every fourth day. Each paroxysm is associated with the ripening of a group of parasites. The parasites in these regularly intermittent malarial fevers exist in the blood in great groups. All the members of each group pursuing their development in unisen and reaching their maturity at practically the same time.
12252 When a group of parasites reaches maturity each parasite breaks up into a larger number of fresh young organisms which attack new corpuscles and begin again their development. The febral paroxysms correspond to the period during which the full grown parasites are breaking up into the new brood. In Tertian fever this period occurs every other day. In Quartan every fourth day. In either instance if multiple groups of parasites be present—groups which reach maturity on successive days, the chills will occur at more frequent intervals.

In infections with the third form of malarial parasite—the Aestivo-Autumnal parasite, the symptoms are somewhat different. These parasites are not as a rule arranged so regularly in groups. The stage of maturity with the liberation of the new group of parasites, does not occur at such regular intervals. Small groups of parasites may be segmenting almost continually. As a result of this one sometimes sees continued fevers

or fevers with irregular intermissions or remissions. The
12253 malaria fevers are recognizable and diagnosticable by
the examination of the blood under the microscope and
the demonstration of the parasites and need never be confounded with typhoid fever. They are also recognizable by the fact that they are curable by quinine. The only patients with malarial fever properly treated, who ever die are certain cases of extremely pernicious Aestivo-Autumnal malarial cases which die within forty-eight hours perhaps of the beginning of the treatment. No case of continued malaria which could be confounded with typhoid fever need ever be fatal. They always clear up under treatment with quinine and no case of continued fever which lasts more than—well to be most generous four or five days after treatment with quinine, is malaria. That is a statement which in my experience can be positively made.

Q. What are the known means of conveying the parasites of malaria whereby the disease is contracted?

A. The only known way by which malaria can be carried
12254 is by the bite of a mosquito. The malarial parasites of
all three varieties posses two cycles, one of which they
pass in the stomach wall, and in the salivary glands in certain types of mosquito-members of the genus anopheles. The other cycle they undergo in the human being. So far as known and so far as believed by all who have particularly devoted themselv to the subject of malarial parasites, they do not exist outside of the human being or the mosquito. If a mosquito of the genus anopheles at a fitting time of the year when the temperature is warm enough, bites a patient whose blood contains certain forms of malarial parasites, at the end of seven or eight days that mosquito will be capable of transferring the infection by bite to another human being. After careful investigation during the last six years——since this discovery has been made—there has not been revealed a single instance where malaria has originated
except in the presence of this type of mosquito. And
12255 furthermore most interesting experiments have shown
that even in the most malarious districts, the disease
may be kept away by thoroughly protecting individuals from the bites of mosquitoes. And on the other hand it has been shown that by taking a given population and treating them

with quinine in such a way that human beings are never allowed to have parasites in their blood, so that the mosquitoes can get them, the disease may be wiped out. Koch has done that in several places, and most striking were his experiments in a town of seven hundred inhabitants in New Guiana or West Africa. He went there before the beginning of the malarial season and put every one who had parasites in the blood under treatment; paid no attention to mosquitoes but watched the people and as a result there was no epidemic. So far as known the parasite does not live in the mosquito for more than several weeks or a month.

Q. Have you ever found the parasite of malaria in the mosquito?

A. Yes, I have. I have fed mosquitoes on patients
12256 whose blood contained malarial parasites and demonstrated intermediate stages in the mosquitoes stomach.

Q. Do you know of any recorded instance where the mosquito has been employed in transmitting malarial fever from one country to another?

A. Yes, that was done in the case of Dr. Manson, the son of Dr. Patrick Manson in London. The Italians—a number of Italian observers had demonstrated beyond a possibility of contradiction the fact that the disease could be transmitted by the bites of mosquitoes with mathematical accuracy and Patrick Manson of London wishing to demonstrate this more impressively arranged that Dr. Bignami of Rome should send him, I think, two mosquitoes which had bitten a case of malarial fever at such a stage that they ought to be capable of transferring it shortly after arriving in London. These mosquitoes were forwarded to London and his son allowed himself to be bitten by them. His son had never had malarial fever which does not exist in London today except as in so far as it is im-
12257 ported; and he developed after a proper period of incubation the characteristic symptoms of Tertain malaria of the same type as that which the patient had who was bitten by the mosquito in Rome. It was simply a dramatic illustration of what the Italians had definitely shown before.

Q. Is malaria as prevalent in the center of a large city as in the suburbs of a large city?

A. No, there are probably very few if any large cities with proper drainage in which the mosquito capable of transferring malaria is found except in the suburbs for the reason that this class of mosquito lives and breeds in shallow pools containing certain sorts of algae for food and does not breed in other standing water in wells and cans and that sort of thing in which the ordinary house mosquito thrives. In Baltimore which is surrounded by a malarious country, especially on the side of the bay, the disease never breaks out in the middle of the town except in individuals who have been exposed in the
suburbs, and with a pretty wide experience, I have never
12258 found the anopheles except towards the outskirts of the
city where there are slowly running streams and pools in which these mosquitoes breed.

Q. How long do mosquitoes live?

A. That varies very much, and just how long a mosquito may live is not definitely known, but mosquitoes hibernate and live through the winter. The anopheles for instance I have found in winter in enormous numbers hanging from the ceiling of cellars and the roofs of barns where they spend the whole winter. In hot weather unless you keep proper food for a mosquito and give him plenty of room to fly about he may die pretty quickly, but I have kept mosquitoes alive for—I think the longest I have ever kept mosquitoes alive was two months. A mosquito has to be fed as a rule about every other day in warm weather. In winter they will hang upon the wall or in a dark place for months, hibernating.

Q. This answer you have just given applies to the malarial mosquito?

12259 A. Yes.

Q. What is intermittent fever and its clinical diagnosis?

A. That is not a very easy question to answer. Intermittent fever is a term—a purely clinical term—describing a form of fever; a fever which has intermissions. Such fevers occur under a great variety of circumstances. The term is very commonly used to describe the regularly intermittent malarial fevers, but used as such it is not an exact scientific term.

Q. What is remittent fever and its clinical diagnosis?

A. The same answer really applies to that as to the last question; it describes a type of fever which may exist under all manner of circumstances. It has been used pretty largely to describe fevers occurring in malarious districts, long continued with occasional remissions and non-resistant to quinine, which were once by a great many people supposed to be malarial in nature, but which are now known to be non-malarial and in a vast majority of instances probably typhoid. The term itself merely describes a type of fever—not a disease.

12260 Q. What is typhoid malarial fever and its clinical diagnosis?

A. Typhoid malarial fever is an incorrect term which was introduced shortly after the Civil War by Dr. Woodward. I am not perfectly sure, it was not introduced during the war—by Dr. Woodward who edited a valuable part of the Medical and Surgical History of the War of the Rebellion. It was used to describe fevers which were supposed to be due to a combination of the malarial and typhoid poison—fevers which were non-resistent to quinine. At the time when the term first came into use neither the cause of malarial or of typhoid fever was known and we did not possess anything like the means of diagnosis which we now have. The term has been entirely abandoned by all competent observers and it is now generally recognized that the disease called typhoid malarial fever—that is the symptoms classed under the name of typhoid malarial fever represent in the vast majority of instances simply un-
12261 complicated typhoid fever. In the statistics of city health departments which are most carefully looked after, all diagnoses of typho-malarial fever are classed as typhoid fever.

Q. What is congestive fever and its clinical diagnosis?

A. I don't know what is meant by congestive fever exactly. That is also purely a symptomatic term. If a person told me that his father or his relative had died of congestive fever, I should think—had he lived in a malarial district—I should suspect that it meant acute pernicious malaria, that is, an acute malignant type of malaria associated with unconsciousness. But congestive fever is a term which means nothing to me—it would simply set me guessing as to what the individual who used the tem, meant.

Q. What is simple continued fever and its clinical diagnosis?

A. Simple continued fever is simply a term used to describe a fever which is not accounted for by the man who uses the term. It is a wholly unscientific term and is a
12262 cloak for ignorance.

Q. Are remittent, intermittent, typho-malarial, congestive and simple continued fevers distinct types of disease and so recognized by bacteriologists and clinicians?

A. No, they are not. They are simply terms describing symptoms.

Q. What significance do you attach to these terms as applied to fevers when they appear in vital statistics?

A. I should regard them as representing in the vast majority of cases typhoid fever.

Q. Assuming that the number of deaths reported as occuring from typhoid fever in the city of St. Louis, as evidenced by the annual reports of the Board of Health of the city of St. Louis Health Department, is as follows:

	1890	140
	1891	165
	1892	441
	1893	215
	1894	171
12263	1895	107
	1896	106
	1897	125
	1898	95
	1899	131
	1900	168
	1901	198
	1902	222
	1903	288

and assuming further that the number of deaths reported in the same reports under the heading remittent, intermittent, typho-malarial, congestive and simple continued fevers, is as follows:

	1890	226
	1891	296
	1892	326
	1893	284
	1894	179
	1895	155
	1896	177
12264	1897	172
	1898	134
	1899	148
	1900	112
	1901	80
	1902	102
	1903	91

do the number of deaths reported as occurring from typhoid fever alone in the city of St. Louis, properly represent in your opinion the total number of typhoid deaths actually occurring in that city?

A. No, I should say unquestionably they do not.

Q. What reasons have you for stating that they do not?

A. I should say in the first place that a considerable personal experience with cases in which these very diagnoses have been made, has shown me that in almost every instance thy represent typhoid fever. I should say furthermore that in an experience of fourteen years in the Johns Hopkins Hospital—I have never made, and I know that there does not stand
12265 on the books a single diagnosis such as appears in the
list which you gave of the remittent, typho-malarial fever and so forth; and further from the fact that the deaths from malarial fever itself in this city and in this neighborhood which is a malarious neighborhood, occur in extremely small proportion as compared with those of typhoid fever—I should say that in view of all these facts as well as in view of the fact that in other cities in which these diagnoses used to be made, they have now been abandoned entirely, these cases all being classed as typhoid fever—in view of all those facts I should

feel perfectly certain in my own mind that the great majority of those cases represent typhoid fever.

Let me say that in my own experience in the Johns Hopkins Hospital since the opening of the Hospital—I have not been here since the opening of the Hospital, I came here the year after it was opened, but I have the statistics of that year—there have been a hundred and thirty deaths from typhoid
12266 fever, just four deaths from malaria, and no deaths ascribed to any of these other causes. Then again the observations of all men of competence who looked into the conditions during the Spanish-American War, show that the diagnoses of typho-malaria, of simple continued fever, of remittent fever as well as the vast majority of the diagnoses of malarial fever, were incorrect; that the condition was purely and simply typhoid fever. And let me add just one more word in regard to the question of malarial fever in particular, and the diagnosis of remittent fever, and all that sort of thing. When a man hands in a diagnosis of remittent fever it is perfectly safe to say that in the great majority of instances he believes its nature to be malarial. Now, those fevers are—anybody who knows anything about practice in this country knows that a case of remittent fever so diagnosticated, is never allowed to go through its course without treatment with quinine; and anybody who has had any sufficient experience with malaria and sufficient
12267 knowledge of its nature, knows that if those cases were malaria not one of them would die; they would all recover.

Q. To what do you attribute the failure of these statistics assumed in the foregoing hypothetical question, to properly disclose the number of typhoid fever deaths occurring in the city of St. Louis?

A. I should attribute it to wrong diagnoses made by physicians in reporting deaths.

Q. Why is it that the doctors employ the terms remittent, intermittent, typho-malarial, congestive and simple continued fevers, for fevers that are recognized as being either typhoid or malarial?

A. The answer to that will be rather long; it is rather hard to answer in a few words: It seems to me that in the first

place it is fair to preface this answer by saying that our knowledge of the nature of malaria and typhoid fever dates in the former instance from '80, and in the latter from '85—that while the discovery of the malarial parasite was made in 1880
12268 and of the typhoid bacillus in 1885, these causes were not generally recognized until at a considerably later period so that many men in the practice of medicine who are in parts of the world or under conditions where they do not follow well the advances of medicine, and many other men who have begun early to grow mentally old, in parts of the world where they could perfectly well keep up with the times, are not familiar with the advances that have taken place. I think however that the great cause lies in the fact that we have in this country no fixed laws governing medical education. In only a very small proportion of the medical schools of this country are men required to have actual clinical experience in the diagnosis of these diseases before they graduate; and I think it is perfectly safe to say that the great majority of young men graduating from medical schools today, in this country, have never followed a case of typhoid fever from beginning to end.

Now, it is perfectly impossible to correctly learn to rec-
12269 ognize typhoid fever without actual bedside experience. In the great majority of medical schools in this country medicine is taught practically by lectures and by books. The students do not have the necessary clinical or pathological experience—they don't know the nature of the disease and they have no experience in observing its clinical course. When they go out into practice a large proportion of the physicians of this country have not been trained and are not able to reason out the nature of the problems before them. When they approach the question of diagnosis of a case of typhoid fever, it is to such men simply a question of matching pictures—they are comparing the pictures they see in bed before them with a picture which has been impressed upon their minds by the lectures or by books which they have read. Now, a man fifteen years ago who was told by his instructor that typhoid fever had certain characteristics and these various other kinds of fevers which, with the advances of our knowledge we know do

not exist as entities, have other characteristics, and has
12270 had few opportunities to control the statements is very
likely to go through his life comparing all that he meets with these pictures impressed upon his mind, fifteen years before. An example of this sort of thing—and it is an example for the necessity of having proper clinical experiments—I have mentioned in an address which I made before the Massachusetts Medical Society a few years ago. A young man, who was not stupid, had graduated at one of the better medical colleges of this country—he had been taught the technique of the physical diagnoses very well—he knew how to detect a patch of pneumonia as well as the next man. He entered into the service of a large hospital in one of the largest cities in this country immediately after graduation. He had never in the medical school followed a case of pneumonia from beginning to end—although he had seen a fair number of cases, of typhoid fever, he had never followed one from beginning to end. Shortly after the
beginning of his services a patient was brought in very
12271 ill who on examination showed a patch of consolidation
in one of his lungs clearly pneumonia. The patient was dull, had oedema of the lungs and was passing a very small quantity of urine, which contained a considerable amount of albumen. The young man had recognized the patch of pneumonia, but the clinical picture which was characteristic was unfamiliar to him. The small quantity of urine and the albumen present lead him to believe that it was an instance of Bright's disease and that the pneumonia was a secondary affair. He was unfortunately left to himself in the treatment of the case and pursued a course of treatment which certainly did not tend to prevent the death of the patient, which occurred shortly afterwards. Now, the picture presented by that patient was perfectly characteristic. Had that student been obliged, as students in England, France and Germany are, to spend a year of his school work practicing in the wards of a hospital, he would have recog-
nized the conditions as easily as possible; as it was he
12272 could not grasp the general picture and was lead astray.

Our standards of medical education are gradually improving, but it is still true in many instances, that young men are turned loose upon the public without the practical experience which is necessary—not only for treatment, but for the recognition of disease.

Q. Do you know of any city in the country where the death rate from malarial fever alone is as high as in the city of St. Louis, as evidenced by the number of deaths, as assumed in the hypothetical question, under the heading, intermittent, remittent, typho-malaria, congestive and simple continued fevers occurring in the reports of the Board of Health of the city of St. Louis, assuming the fevers under those headings to be malaria and not typhoid.

A. In connection with that question I may say that I looked up a few days ago the statistics of several cities with regard to that point and have found some rather interesting facts.
12273 I looked up the statistics of the cities of New York, Brooklyn, Philadelphia and of Baltimore. I obtained these from printed copies of the reports of the boards of health of these cities which I obtained from the Surgeon General's library in Washington.

The mortality for Brooklyn shows some very interesting points. I have here the records of mortality from typhoid and malaria for every year from 1876 to 1903. In 1876 there were reported 97 deaths from typhoid, and from malaria one hundred and thirty seven. Gradually the number of deaths from typhoid tended to increase while those from malaria tended to diminish. In 1889 for instance, there were one hundred and sixty-one deaths from typhoid and one hundred and eighty-two from malaria. In 1890 there were one hundred and eighty-two deaths from typhoid and one hundred and sixty-eight from malaria. In 1896 there were one hundred and sixty-three from typhoid and one hundred and forty-eight from malaria. In 1898
12274 two hundred and seventy from typhoid and ninety from malaria, and finally in 1903 I find two hundred and sixty-seven from typhoid and thirty-six from malarial fever, showing that while in years past, the deaths from malarial fever were relatively as high as those reported in St. Louis, gradually the deaths from typhoid have increased and the deaths from malaria have diminished. The proportion of deaths from typhoid to the deaths from malaria was in 1890 as 1.08:1.; in 1903 7.4:1.

Now, in the city of New York we find a similar change though there the deaths from all cases reported as typho-malaria in 1890 were classed as typhoid. In New York in 1890 there were 352 deaths from typhoid and one hundred and seventy-six from malaria—in 1900 342 from typhoid and 68 from malaria—in 1901 380 from typhoid to 49 from malaria—in 1902 366 from typhoid to 52 from malaria, and in 1903 317 from typhoid to 27 from malaria.

12275 That is the proportion of deaths from typhoid as compared with the proportion of deaths from malaria was in 1890 as 2: 1, and in 1903 as 11.7 : 1.

Now, in Baltimore a very similar state of things exists. In Baltimore I was unable to get the statistics for 1890. In 1891 there occurred one hundred and fifty deaths from typhoid fever, from malarial fever twenty-six, and from these other classes of fevers, including thirty-nine "typho-malaria," sixty-five. Since 1897 all the "typho-malarias" have been classed as typhoid. I do not believe I am justified in saying that positively; I think that is the case. Since 1898 all these nondescripts supposed to be malarial fevers have been classed under the bad heading of intermittent fever. I find in 1899 the proportion of typhoids to these nondescripts is one hundred and fifty-three to forty-eight. There is no special heading of "malarial fever." 1900 one hundred and eighty-nine to fifty-four—1901 one hundred and forty-one to thirty-six—1902 two hundred and 12276 twenty to thirty-one. I was unable to get the statitstics for 1903. You see there again the same change; relatively more diagnosis of typhoid fever and very much less of the others.

Lastly I looked up the statitstics of the city of Philadelphia. These are interesting in that in Philadelphia the statistics have been much more carefully controlled. The fevers there are included under three headings: the typhoids, the malarias and another group which are entered in their records as "remittent fevers," "catarrhal," "gastric fevers," and so forth. There are one or two deaths every year under these headings. These are, I believe—I am personally convinced, typhoid fever; however, I have made these three hadings. In 1890 there were six hundred and sixty-six deaths from typhoid fever to thirty-four from malaria and twenty-four of these indeterminate fevers, including fourteen cases of remittent fever.

12277 In 1901 there were four hundred and forty-four cases of typhoid fever, fifteen of malaria and twelve of indeterminate fevers. The relative proportion between the diagnoses of typhoid and of the indeterminate fevers, including malaria, was as 11.4 : 1, in 1890 and as 16.4 : 1, in 1903.

During the whole of the fourteen years since the opening of the Johns Hopkins Hospital—or nearly fifteen now, there have occurred, as I stated before, one hundred and thirty deaths from typhoid fever, and four from malaria, the relative proportion being as 32.5 : 1.

As one compares these statistics with the statistics of St. Louis, it will be found that those of Brooklyn show at certain times even a larger proportion of the so-called malarial fevers than were present in St. Louis, but that the same change has taken place here as has occurred in St. Louis—the diagnoses of malaria have diminished, and the diagnoses of typhoid fever relatively increased.

12278 MR. JEFFRIES: I move to strike out all the tables this witness has read into the record for the reason that the same are incompetent and irrelevant.

MR. TODD: Q. Were the tables which you read into evidence taken from the official records of the different Boards of Health?

A. They were.

MR. JEFFRIES: I object to the question and renew my motion to strike out the answer.

MR. TODD: Q. What proportion of the deaths in the column under the heading "typhoid, intermittent, remittent, conjestive and simple continued fevers" assumed in the foregoing hypothetical question as occurring in the city of St. Louis as evidenced by the report of the Board of Health in your opinion should be classed as typhoid?

A. Well, I should say that a perfectly safe estimate would be at least seven-eighths. Seven-eighths of those were typhoid fever. If one desired to get the relevant frequency of typhoid fever from year to year I think that the adding together of the two columns would give as correct an idea as any other method.

Q. What proportions would you class as malarial fever?

12279 A. That is of course a very difficult question to answer positively. From the comparisons of these statistics with those of other cities—from the general conditions which exist so far as I know them, I should think it would be fair to take the proportion as shown by the statistics in the Johns Hopkins Hospital. That is proportionately or approximately 30 to 1 in favor of typhoid—that is, out of the total statistics added together.

Q. What do you do with the difference between the one-eighth and the one-thirtieth which you class as malarial?

A. I should think that would be a fair allowance, a very fair allowance for the cases of general tuberculosis, or ulcerative endocarditis and other general septicemias of various orgin.

Q. What do the mortality statistics of malaria show in cities where careful attention has been paid to malarial fevers as regards the number of deaths occurring from malarial fever?

A. There are no cities I believe in this country which give really an accurate representation of the proportion of deaths from malaria. The city of Philadelphia would seem to me to give the fairest representation of this question and that I have already quoted where the deaths from typhoid fever in
12280 1901 were 444; from malaria 15, and from various other
indeterminate conditions 12. I believe that the proportion, the proportion of deaths included under malaria, is too large even there, but it approaches the correct figures much more there, I believe, any other city which I have examined.

In Baltimore we have, 1902, 220 deaths from typhoid fever and 31 from "intermittent fever," which is supposed to be malaria. I am sure from my observations here that that is an over estimate of the deaths from malaria—from my observations which have been made in connection with the Johns Hopkins Hospital where we get a fair general run of cases as they enter the hospital.

Q. It is generally recognized by bacteriologists and clinicians that classifying typhoid fever in one column, intermittent, remittent, typho malaria, congestive and simple continued fevers in another column in board of health reports of cities is an improper classification from a scientific standpoint as affording a true indication of the mortality from typhoid fever and malaria?

A. It is recognized by all competent observers that such a method of representing the mortality from typhoid fever is entirely incorrect.

Q. Assuming that the reports of the board of health of 12281 the city of St. Louis by the month from 1895 to 1903, inclusive, under the heading typhoid fever, which for the purpose of convenience is designated A in the tables as follows, and as intermittent, remittent, typho malaria, congestive and simple continued fever for the sake of convenience is designated as B in the table that follows, which table prepared and sworn to by Professor Jordan is based upon said reports and is as follows:

12282

ST. LOUIS.

	1895		1896		1897		1898		189	
	A.	B.	A.	B.	A.	B.	A.	B.	A.	B.

A.—Typhoid fever.

B.—Remittent, intermittent, typho-malarial, congestive and simple continued fever.

12284 Q. Will you please state what construction you place upon this table as showing the relative mortality from typhoid fever and malarial fever in the city of St. Louis during the periods covered by the foregoing table?

A. I should regard these tables as indicating that the mortality from typhoid fever had fluctuated more or less from year to year. That gradually in the last thirty years an improvement in the accuracy of the reports from the general physicians had taken place so that cases of typhoid fever which had previously been included in column B had been properly reported as typhoid fever. As to the relative frequency of typhoid fever and malaria it would seem to me that it would be impossible to draw definite conclusions from these tables, though as to the prevalence of typhoid fever I should think that one might draw good conclusions.

I should think that the mortality from typhoid fever had varied from time to time, from year to year; had risen slightly during the last two years, but that the fluctuations were no more than such as had previously occurred and were not such as to justify any direct assumptions in regard to the cause.

12285 Q. From a careful consideration of the tables which have just been assumed in the hypothetical questions, what conclusions would you draw as to whether the outbreaks of fever in St. Louis were of an epidemic during this period or of a normal death rate due to local causes or otherwise?

A. In the year 1892 I should suspect that there had been some definite epidemic, but since that time the variations shown are not such as to suggest to me any striking special cause. They are variations such as occur in most cities in this country from time to time without explanation.

Q. Assume that the added totals of tables from typhoid fever and the tables from remittent, intermittent, typho-malarial, conjestive and simple continued fevers, as they appear in the report of the board of health of the city of St. Louis, as heretofore given in evidence are as follows:

12286 ST. LOUIS.

Population 1900, 575,238.

Year	Typhus........ Typhoid Fever .	Reported deaths from Remittent, Intermittent, Typho-malarial, Congestive and Simple Continued Fevers.	Total ....
1890	140	226	361
1891	165	216	381
1892	441	326	767
1893	215	284	499
1894	171	179	350
1895	107	155	262
1896	106	177	283
1897	125	172	297
1898	95	134	229
1899	131	148	279
1900	168	112	280
1901	198	80	278
1902	222	102	324
1903	288	91	379

12287 What do those totals as above indicated represent in your opinion as to the mortality condition of the typhoid fever in the city of St. Louis, covering the period as above indicated after allowing the said remittent, intermittent, typho malaria, congestive and simple continued fever column, such proportion as being typhoid fever as in your opinion you should allow? What is your opinion, based upon the statistics as assumed in the foregoing hypothetical question as to typhoid deaths under the remittent, intermittent, congestive and simple continued fever tables in the city of St. Louis as to whether the said statistics show an increase or decrease in the typhoid fever mortality in the city of St. Louis since the year 1899; eliminating the year 1892 which is a year of special epidemic?

A. I should regard this table as indictaing only variations in the typhoid mortality, such as I stated a moment ago might and do occur in many cities without any definite explanation being found.

The typhoid mortality I should say had rather decreased, tended on the whole to decrease from 1893 down to 1901. During the two years following 1901 there has been a
12288 slight increase, but that increase is not, it seems to me, more than might occur without any special change in the pre- existing conditions.

Q. Assume that two circular letters, one issued in the fall of 1900 and another issued in the fall of 1901 were issued by the health commissioner of St. Louis calling the attention of physicians to the fact that the law requires them to report all cases from typhoid and all deaths from typhoid, and at the time that letter was sent out the question of opening the drainage canal was being agitated in the public press of St. Louis and there was considerable discussion and an investigation was going on at that time of the analysis of the samples of water collected and was attracting considerable attention. On your examinations of the statistics of St. Louis as heretofore assumed in the hypothetical question heretofore asked you for the years 1900, 1901 and 1902 as compared with previous years, does the effect of such a letter, assuming that the same had been sent out to the doctors by the health department of St. Louis, manifst itself in those statistics?

A. Yes, I should say that it certainly did.

Q. In what way does the effect of such a letter appear from the statistics?

12289 A. It appears in the relative increase in the number of deaths reported in the typhoid column as compared with those in the column of remittent, intermittent, malaria, congestive and simple continued fevers. It would indicate to me that, stimulated by the advice of the board of health, the physicians had made more accurate and careful diagnoses.

Q. From your examinations of the typhoid and typho-malaria group of deaths as assumed in the foregoing hypothetical question what is our opinion as to whether these two tables taken separately correctly show the typhoid conditions of the city of St. Louis for the period mentioned?

A. No, I do not think taken separately they show at all satisfactorily.

Q. Upon what do you base your opinion that they do not correctly show the typhoid conditions in the city of St. Louis, taking them separately?

A. Upon the facts that I have already mentioned, namely, that everything in my experience and study go to show that the diseases included under such headings as these are in a vast majority of instances typhoid fever.

Q. From your knowledge of these classes of fevers mentioned in the two columns of vital statistics as heretofore assumed, how should they be treated by a bacteriologist, clinician and statistician in order to arrive at the true typhoid fever mortality in the city of St. Louis? 12290

A. Well, as I said a little while ago I should say that a safe estimate of the typhoid fever mortality might be gotten by adding to the typhoid column seven-eighths of the cases coming from the other causes. I should say that a fair estimate might be obtained probably from the comparison of the number of deaths from year to year by adding the two columns together.

Q. What are the sources of infection generally obtaining in large cities which accounts for the prevalence of typhoid fever in cities?

A. I should say that the introduction of the typhoid bacillus into large cities occurs probably in most instances through the water supply, dairy products, uncooked vegetables, such as lettuce, celery and other articles of food; that in cities in which drainage is not good, in which water closets or wells into which the drainage goes, are open, typhoid fever may readily spread after it has started; doubtless this is largely through the instrumentality of flies, while on the other hand, if there are wells from which the water is drunk, the disease might easily spread and does spread in a great many instances by the infection of those wells. 12291

Q. Assume that in the city of St. Louis in 1895 there were in the neighborhood of 4800 wells, and assume further that the board of health of the city of St. Louis authorized an examination of those wells by the city chemist and after an examination of about 50 of those wells, all of which were found to be contaminated, and were condemned by the city chemist, that the board of health passed an order instructing the city chemist to stop the examination of city wells until further ordered, and assume that the water from those wells was used by the citizens of St. Louis, would the presence of such a number of wells in a city in your opinion have any effect upon the typhoid conditions of such city?

A. Yes, I should think that the chances were that they would; that such wells would be a menace to the health of the city and that it would be very possible that certain of the wells might become infected and serve to spread the disease.

Q. Where typhoid fever is due to infected water supply,
12292 how does it manifest itself in its vital statistics?

A. In those cases in which infection of water supplies have been definitely or fairly definitely proven, it is always, I think, to my knowledge, manifested by an explosive epidemic.

It is common to assume in cities, such, for instance, as the city of Baltimore, where we know our supply is open to contamination, it is common to assume that cases are dependent upon the water supply, but as a general rule where it can be proven that the water supply going to a whole city is infected there is an explosive outbreak and it seems to me it would be very difficult to prove the instrumentality of a general water supply to a city in producing typhoid fever unless such an epidemic occurred. I should expect with seriously infected water supply such an epidemic to occur.

Q. From your study of the typhoid statistics of St. Louis as assumed in the foregoing hypothetical question, do those statistics indicate an explosive epidemic within the meaning of the answer which you have just given?

A. No, I think not.

Q. Have you made a study of comparisons between typhoid and typho-malarial groups of the city of St. Louis with
12293 those of any other city?

A. I have.

Q. Assume that the following table testified to in evidence by Professor Jordan is correct as compiled from the typhoid fever and typho-malarial columns of mortality statistics of the health reports of the city of St. Louis for the years 1890 to 1900, according to the United States census report, and the intervening years estimated by Farr's Formula, which table is as follows, and based upon the population of the city of St. Louis:

12294

ST. LOUIS.

TYPHOID FEVER DEATH RATES.

Year..............	Population	Death Rate per 100,000.		
		Typhoid Fever alone	Typhoid Fever plus 50 per cent of deaths recorded under heading intermittent fever, etc.	Typhoid Fever, plus all the deaths recorded under heading intermittent fever, etc.
1890	451,700	30.0	56.67	81.2
1891	462,763	35.6	56.98	82.3
1892	474,077	93.0	127,40	161.7
1893	485,668	44.2	73.52	102.7
1894	497,565	34.3	52.24	70.3
1895	509,740	29.9	30.35	51.3
1896	522,225	20.2	37.37	54.1
1897	533,762	23.4	39.53	55.8
1898	548,590	17.3	29.53	41.7
1899	561,510	23.3	36.49	49.6
1900	575,238	29.2	39.07	48.6
1901	589,315	33.5	40.39	47.1
1902	603,736	36.7	45.21	53.6
1903	618,510	46.5	54.0	61.3

12295 Will you please state what is your opinion, based upon the tables heretofore read as to whether typhoid fever has increased or decreased in the city of St. Louis since 1900 over the conditions that obtained in St. Louis prior to 1900, eliminating 1892 a year of special epidemics?

MR. JEFFRIES: I object to the question for the reason that the table shows for itself.

A. I should say this table indicated that during the past two years there has been a slight increase in the typhoid mortality, but that this increase had been preceded by a diminution and on the whole a gradual diminution from 1892 down to 1901.

I should hesitate from these figures to assert that the mortality had permanently increased or I might say that to look at such table I should not regard it as having greatly increased, and I should want to see what happened in 1904 before expressing any opinion.

The increase in 1902 and 1903 seems to me not more than might occur with fluctuations such as are observed in the tables which I have mentioned from New York, Brooklyn and other cities.

12296 Assuming that during the last two years in the city of St. Louis that a great number of laborers and visitors came to the city for the purpose of assisting in the construction and building of the World's Fair at that point, would the presence of such a number of people in a city the size of St. Louis afford any explanation for the seeming increase of typhoid fever in 1903 over 1902?

MR. JEFFRIES: I object on the ground that the question is speculative.

A. It seems to me that that is a question that would be difficult to answer positively.

If those individuals came from regions where they had not been subjected to typhoid fever at all to a town in which the relative typhoid mortality was rather high, they would probably add to the death rate.

If on the other hand they came from cities where they had been for years exposed to an actual chance of infection I can not see that it would have any effect.

Q. Assume that the typhoid deaths as reported in the typhoid fever column of the city of St. Louis are correct, and assume that
in 1899 the increase over 1898 was 34.7 per cent.,
12297 and in 1900 the increase over 1899 was 25.3 per cent.,
and in 1901 the increase over 1900 was 14.7 per cent.,
and in 1902 the increase over 1901 was 9.5 per cent.,
and in 1903 the increase over 1902 was 26.7 per cent.,
and assume that the increase of 1903 over 1902 is less than the increase in 1899 over 1898, and assume that from 1898 to 1902 there has been a gradual decrease in the percentage of increase during these three years, would you say the increase as indicated by the percentages assumed in my question were abnormal or normal increases for a city the character of the city of St. Louis and the size of the city of St. Louis?

MR. JEFFRIES: I object to the question for the reason that the table shows for itself.

A. You were speaking not of the number of deaths, but of the death rate, were you not?

MR. TODD: Q. Yes, the death rate per 100,000.

A. It does not seem to me that any increase in death rate can be regarded as normal. I should say that such figures as these would perhaps not suggest any striking change of the conditions for the worse, but I should regard any increase nevertheless as a change of conditions for the worse.

12298 Q. Would you regard the conditions obtaining between 1898 and 1899 as better or worse than those conditions obtaining in 1900 and 1901?

A. Assuming all the time that the figures of typhoid mortality are correct, the figure depending upon the single column—

Q. (Question repeated.)

A. It seems to me the conditions between 1898 and 1899 are worse than those between 1900 and 1901.

Q. Do you know how the typhoid fever death rate in St. Louis compares with the death rate of other American cities during this period, eliminating from the St. Louis records the year 1892, which was conceded to have been a year of special epidemic?

A. I made no extended investigation on this point, but I have here a list of the typhoid mortality taken from the special report on the statistics of the cities of the United States of 30,000 population and upward compiled by the United States Department of Labor. This is taken from the public health reports issued by the Treasury Department, public health and marine hospital service, Volume 19, No. 1, pages 4 and 5. This table
includes the death rates for the year 1901, the last avail-
12299 able year at that time for 100,000 population. It in-
cludes all cities with a population above 30,000 excepting the city of Chicago, from which the data were not to be secured at that time.

These rates run from 9.7 per 100,000 at Savannah, Georgia, to 124.7, Pittsburg, Pennsylvania.

Taking those 69 cases, we find that beginning with Pittsburg, the highest mortality, the 34th town, Evansville, Indiana, has a mortality of 26.6 per cent. and Providence, Rhode Island, 26.4, the 35th town.

It would be seen therefore that the death rate from typhoid fever in St. Louis for that year,—the reported death rate, was 33.3 per cent.,—is relatively high, though St. Louis at that time stands 24th, that is, the 24th city in the list, beginning at the end of highest mortality.

The death rate would seem to me, then,—particularly in view of the conditions existing before and after,—would seem to me to be relatively high as compared with the reported death rates of other cities.

Q. From a careful analysis of the typhoid and typho-malaria
mortality statistics as they appear in the foregoing hypo-
12300 thetical question and from your knowledge of conditions
that obtained in other cities, a water supply from a
river, as well as all other sources of knowledge which you possess upon this question, what is your opinion as to whether there has been an increase of typhoid fever in the city of St. Louis since January, 1900, over typhoid conditions that prevailed in St. Louis for ten years prior to that time? Basing your estimate of typhoid conditions upon your judgment as to the typhoid conditions as evidenced by the typhoid death rate column and the typho-malaria column heretofore assumed?

A. There seems to me to have been an increase. Not a great increase but an increase.

Q. Is there such an increase as you would attribute to any special cause?

MR. JEFFRIES: I object to the question for the reason that the witness has not acquainted himself with the local conditions of St. Louis so as to be able to express an opinion as to whether it should be attributed to any one or more causes.

A. There is nothing in these figures to suggest to me any definite special cause.

I may say there is enough to make me feel I should want
12301 to look around for something but there is nothing in
these figures that would suggest a definite cause to me.

Q. From a consideration of the statistics heretofore assumed in evidence what is your opinion as to whether the typhoid conditions in the city of St. Louis has been epidemic in their character since 1900 over the conditions that obtained there prior to 1900, eliminating 1892?

A. I must say that I should be inclined—perhaps this is quibbling—to regard in any city with a typhoid mortality such as that St. Louis has or that which we have in Baltimore,—to regard typhoid fever as epidemic, but I should not consider the conditions in the last several years in St. Louis such as to suggest that any striking change had taken place in the general conditions that obtained prior to that time.

I think it is fair to say that any increase occurring two years in succession should always make one look for something, but I should not regard it as particularly suggestive if the assumptions made in the earlier question in regard to the condition of wells in the city of St. Louis are true.

12302 CROSS-EXAMINATION, by Mr. Jeffries.

Q. Doctor, I understood you to say that in your opinion seven-eighths of the intermittent, remittent, typho-malarial, etc., reported in the health reports of the city of St. Louis and other cities should be taken as the typhoid fever and considered as such?

A. Well, I think I said that in regard to the St. Louis statistics, not of other cities necessarily, because they vary.

Q. Now, prior to 1900 there was a greater number, according to your testimony, of cases of malarial, remittent, intermittent, etc., fevers reported in that city per 100,000 population than since that time, Is that so?

A. As I remember my testimony here the proportion of deaths under column B as compared with the deaths under column A was in the earlier years a little higher than it was in the later years.

Q. Do you know that that difference in the reporting of the cases was not caused by a diminution in number of deaths from fevers other than typhoid in the city of St. Louis, or do you base your answer altogether upon an opinion which you formed from an examination of the statistics which were presented to you? 12303

A. Well, I base my answer on the statistics as they are presented to me, on what I have seen, and in view of the conditions elsewhere. I was influenced very largely by the fact that with the exception of the two years, 1892 and 1893, the general totals of the cases reported in column A and column B were pretty nearly the same, while the relative proportions were different.

Q. Assuming, Professor, a patient takes ill with fever and remains so for several months and finally dies, and the death is reported as intermittent or remittent fever, would you say that was malarial fever or typhoid fever?

A. Of course, the points which you assume there are hardly enough to justify a very definite opinion. I should, if that case had been treated with quinine, and the fever had not broken, assume that it certainly was not malarial fever.

Q. Would you assume that it was typhoid fever?

A. I should not have grounds enough for a definite assumption, and I should have one ground for thinking that it
12304 might not be typhoid, that it lasted for several months.
Typhoid fever often does last as much as eight weeks, but it is not the rule.

Q. Is it not a fact that when typhoid fever does last as long as eight weeks it is a very severe case of typhoid?

A. Not necessarily. There may be cases that are not especially severe in themselves, but with relapses—where there is a rise in temperature before the fever has quite reached normal—of which there may be several, without the development of any very severe symptoms. Such a case may last several months. It may be long but not necessarily very severe.

Q. And those cases are very rare, are they not?

A. They are not very common lasting as long as that, lasting for several months.

Q. Assume, Professor, that a person should have malarial fever, or what was commonly diagnosed as malarial fever, running through a period of months, and finally died, and the physician would diagnose that death as of congestive chill, would you determine that as typhoid fever?

A. That again is rather a hard question to answer definitely. What do you mean by having a disease commonly diagnosed as malaria which has lasted through this long period of time?

Q. I mean that the malaria occurs at intervals, for
12305 weeks, for days at a time, in which there would be days
there would be no malaria present and the patient apparently relieved of the disease, but afterwards occurring again?

A. I should have to know more of that individual case to express an opinion.

Q. Might not a death of that kind occur and be reported as a death caused by congestive chill which would not be typhoid fever?

A. Yes, and I should be glad to say one thing more, that I do not believe the majority of deaths reported from congestive chill are typhoid fever. I believe that typhoid fever accounts for few, if any, deaths, with that particular diagnosis.

Q. In order that the subject of congestive chills, that the subject of congestive malaria—might not the words chill and malaria be given the same meaning?

A. It may mean that and it may mean something else.

Q. Now, then, what else may it mean?

A. That is a question to which the answer must be purely speculative. The term congestive chill is popularly supposed to mean pernicious malaria, comatose malaria. It seems to me it would be rather idle to speculate what else it might be.
12306 I do not remember ever to have seen an autopsy on a case which the diagnosis, congestive chill, was made. I can conceive that the term congestive chill might be used in connection with certain very acute infections and especially in connection with acute cerebro-spinal meningitis. Those are two conditions I should imagine it might be employed for, but it is purely speculative.

Q. Then, as to whether or not a death which is reported as being caused by congestive chill was typhoid fever or not depends a good deal upon the history of the case, does it not?

A. Very much and I am perfectly frank to say that I should not be inclined to interpret the diagnosis of congestive chill as typhoid fever. If there was any reason for doubting its being malaria I should be much more inclined to think that it was a very malignant attack of cerebro-spinal meningitis or something else, not typhoid.

Q. Now, then, may not certain cases of malaria fever reach a condition that after some other complications had set in that death might be produced, then they would be reported out as malaria fever?

A. Do I understand you to say that some case of malaria fever might have another complication?

Q. Yes, which would produce death and yet at the same
12307 time be reported as malaria fever?

A. It does not seem to me to be possible to deny that such a thing might occur.

Q. In cases of malarial fever and other fevers, such as intermittent and remittent which are not thoroughly understood, in which other complications are liable to arise which would produce death and the deaths reported under the heading which the physician had believed the patient to be infected with?

A. I should think that would be very unlikely.

Q. You think that does not occur in any instance?

A. No, I should not say that. I should think it was possible, but in cases of that sort which are supposed to be malaria, which are treated with quinine and react quickly it would be very likely to be recognized if a complication occurred.

Q. Do you know whether all physicians use quinine for malaria or not?

A. I never heard of a physician who did not use quinine for malaria.

Q. Do you know whether or not there are physicians who do not prescribe quinine for anything?

A. There are physicians who do not prescribe quinine for anything?

12308 Q. Yes, and absolutely refuse to do it?

A. I can not imagine a man in his right mind doing such a thing,—a man with a reasonable education.

Q. Have you ever examined the mortality records of the city of St. Louis personally?

A. Only those which have been presented to me as sworn to by Professor Jordan.

Q. Have you ever examined any original records of the city of Baltimore?

A. Well, I have examined the health reports.

Q. The published reports?

A. Yes, sir.

Q. And that was true with all of your testimony?

A. Yes, sir.

Q. Why did you exclude the one-eighth of the column B, known as remittent, intermittent and malaria, from the typhoid list?

A. That was done purely as an approximate estimate and based on my experience and general information.

Q. Does that one-eighth apply to all the cities in the United States?

A. No, I do not think it does. As I endeavored to show by
the statistics there are very great differences, for in-
12309 stance, between the cities of Philadelphia, Brooklyn and
New York. Now, the surroundings of Philadelphia are
certainly more malarious than the surroundings of New York,
and yet the reported deaths from malaria are materially greater

in New York, until very recently, than they have been for the last ten years in Philadelphia.

Q. What other fevers produce death besides typhoid fever?

A. A very long list of general septicemias of all sorts and kinds. Most infectious diseases produce fever and death may occur in all the more serious. For instance, pneumonia, which is a septicemia—general infections with streptococci and staphylococci, all the contagious diseases which we believe to be infectious and which we believe to be due to infectious agents, such as smallpox, diphtheria, scarlet fever, measles, acute rheumatism, cholera—

Q. And a long list of miscellaneous fevers?

A. Yes, sir, a long list.

Q. In all cities, Doctor, typhoid statistics vary, do they not, from year to year regardless of how perfect the water supply may be, to some extent?

A. So far as I know they do and I should certainly
12310 think they would.

Q. And these variations are shown from month to month and year to year, are they not?

A. Yes, sir, with, as a rule, certain general points in common each year; in that ordinarily typhoid fever is more frequent in the late summer and fall months.

Q. This variation may be due to a variation in sanitary condition of the water supply, may it not, as well as other things?

A. I think it would be difficult to deny that it might not.

Q. The water supply is liable to vary in its sanitary condition as well as in other conditions?

A. Yes, sir.

Q. Wells do not necessarily produce typhoid fever?

A. Only when they are infected.

Q. The best way to determine whether or not wells do produce typhoid fever or have an effect upon the typhoid mortality of the city is by comparing the health of the community where these wells are located with the health of the people using the public water supply, is it not?

A. Yes, provided, of course, it can be shown that the water from the wells is drunk more by people in the neighbor-
12311 hood than by people coming from the outside.

Q. They usually are, are they not?

A. I should say that they usually were and yet I can conceive an instance, a case in point. There is a well out here in the western part of Baltimore at which every electric car used to, and I suppose still does stop, and the motormen and conductors get off and take a drink. I fancy if you take it day in and day out the well is more drunk from by car conductors and motormen than by people in that neighborhood.

Q. That is a violent exception to the general rule, is it not?

A. Well, I should think that it might be.

Q. Including, Professor, all of the fevers, typhoid, remittent, intermittent and malaria which occur in the city of St. Louis as shown by the health reports and assumed by the hypothetical questions asked you by Mr. Todd in your direct examination I will ask you if it is not a fact that from 1893 to 1899, inclusive, that the general tendency of the typhoid fever mortality of the city of St. Louis is towards a reduction rather than an increase?

A. Yes, excepting between the years 1898 and 1899, there
is no striking increase. Between the years 1896 and 1897
12312 there is an increase of a little over 1 per cent., but of
course between the years 1898 and 1899 there is a distinct increase.

Q. Speaking generally of conditions that existed in the city of St. Louis from 1893 to 1899, inclusive, taking into consideration the typhoid fever death rate and including as typhoid remittent, intermittent, malaria, etc., occurring in that city, based upon the number of deaths per 100,000 as reported in the hypothetical question put to you by Mr. Todd there has been a gradual decrease, has there not?

A. Yes, with one exception, that between 1898 and 1899, there is an increase which is comparable with that which occurs between 1902 and 1903.

Q. And for that year there is a very great reduction to what there was in 1893, is there not?

A. Yes, materially.

Q. How great a reduction?

A. Well, in 1893 the death rate was 102 for the two columns put together, 102.7 per 100,000, and in 1899 49.6.

Q. Now, then, I will ask you if from 1900 to 1903, inclusive, taking the same column into consideration, the same mortality record, to wit: the typhoid remittent, intermittent, malaria, and counting them all as typhoid if there has not been a 12313 gradual increase or rather the tendency has not been to an increased rate per 100,000?

A. It has been in the last two years, yes. Between 1900 and 1903 the rate has increased. Slightly decreased between 1899 and 1901.

Q. The tendency in one instance, however, has been to increase and in the other to decrease, taking the table as a whole and looking at it?

A. Yes, as far as it goes I should say it had been.

Q. Have you ever examined the death report of the mortality record of the city of Chicago?

A. I have not.

Q. Is there any such thing as congestive fever, pure and simple?

A. Well, I do not know what that means. The term congestive is a physiological term, meaning the filling of vessels, and congestive fever does not mean anything to me.

Q. It does not mean typhoid, does it?

A. Congestive fever as such—I should not have any idea what it meant.

Q. It may mean one thing and it may mean another?

A. Yes, sir.

12314 Q. In other words, as far as the medical science is concerned then it is an unknown quantity?

A. As far as the name alone goes, congestive fever, yes.

Q. And what is true with reference to congestive fever is also true with reference to remittent and intermittent fever?

A. No, I do not think it is.

Q. Now, what is remittent and what is intermittent fever?

A. Remittent and intermittent fever describe a long continued fever as a rule, and as used in the medical profession mean a fever that is rather continued in the one instance with remissions which do not quite go down to normal and in the other with the temperature actually reaching normal and going up again?

Q. Might not also they be malaria, either of those remittent or intermittent?

A. Yes, remittent or intermittent fever terms may mean

malaria. I should like to make one addition—*Not,* I should say with regard to death reports. I think it makes a material difference. I have seen cases of remittent and intermittent fever which were so diagnosticated and were malaria, but people do not die of it; they are cured by quinine. And I have seen such cases that do not react with quinine; in a great majority
12315 of instances these have been typhoid fever and never malaria.

Q. It may be something else besides typhoid fever, may it not?

A. Yes, sir.

Q. It may be a different complication altogether?

A. Yes, there may be infections of another sort.

Q. As a general proposition, Doctor, how long does a case of typhoid run?

A. As a general rule about three weeks.

Q. And the duration of its running is largely limited by the severity of the attack?

A. Well, I think that depends a little upon how one uses the term severity. As I said a moment ago you may have a case of prolonged duration which never manifests any symptoms which give you any alarm. It may be a mild case, but one of long duration, and you may have a case which will last not more than three weks and yet for a week of that time or even more may give you the gravest apprehension. As a general rule, I think it is fair to say that long cases are apt to be severer than others, but there are many exceptions to it.

12316 Q. A good deal then depends upon the resistant force of the patient?

A. Very much.

MR. TODD: I have no re-direct examination.

W. S. THAYER.

Adjourned until Monday, March 28, 1904, at 9:00 a. m., room 710, City Hall, Philadelphia, Pennsylvania.

12317 State of Missouri
vs.
State of Illinois and Sanitary District of Chicago.

Parties met pursuant to adjournment.

Room 710, City Hall, Philadelphia, Pa.

Monday, March 28, 1904, 9:00 a. m. Present the Commissioner, S. B. Jeffries, Esq., representing complainant, James Todd, Esq., representing defendants.

JOHN W. HILL,

a witness called on behalf of the defendants, after being duly sworn by the Commissioner, was examined in chief by Mr. Todd, and testified as follows:

Q. What is your name?

A. John W. Hill.

Q. What is your business?

A. I am an hydraulic engineer.

Q. Where are you engaged?

12318 A. At the present time I am employed by the city of Philadelphia as chief engineer of the Bureau of Filtration, a bureau that is conducting the general improvement of the water supply of that city.

Q. In what manner is this bureau attempting to improve the water supply of Philadelphia?

A. Chiefly by filtration of the Delaware and Schuylkill River waters which now and hereafter will form the sources of public water supply for Philadelphia and partly by reducing the consumption of water from the Schuylkill River, and increasing the consumption of water from the Delaware River.

Q. How large is the plant over which you preside as chief of the Bureau of Filtration that is being constructed for the city of Philadelphia?

A. If by magnitude is meant the extent of the works, it embraces as a first proposition the filtration of 320,000,000 gallons of water per day of 24 hours, the transfer of the chief source of supply from the Schuylkill to the Delaware River, and a general re-organization of the distribution system brought about by reason of the principal volume of water in the future coming from the Delaware instead of the Schuylkill River. It

will involve a cost of about $26,000,000.00. Of that amount
about $17,000,000.00 worth of work has been accom-
12319 plished at the present time. Part of the system of fil-
tration is now in daily operation and has been for a
period of twenty months.

Q. When did you first begin the study of sanitary problems?

A. At the time when I first engaged in the planning and building of works of public water supply, I should say about 32 years ago. From that time up to the present date information touching the hygienic quality of water supply has always been interesting and as a rule an essential part of my work.

Q. What work have you done or been actively connected with in connection with sanitary problems?

A. I have been associated with about 60 works of public water supply, including different questions looking either to the general construction or improvement of municipal waterworks. Wherever my engineering association with public water supply has touched the question of a water quality, investigations have been made to determine the desirability of available sources.

Prior to coming to Philadelphia four years ago my prin-
cipal work along this line was in behalf of the city of Cincin-
nati, where I was chairman of the original board of en-
12320 gineers that made an investigation and furnished the
plans upon which the present improvements at that point
are being constructed. As a part of the Cincinnati work and for other cities for which I have done engineering along the Ohio River, investigations have been made at Parkersburg, Madison and Jeffersonville, Indiana, to determine the desirability of drawing water from the Ohio River for drinking and other domestic uses. The same investigations have been made in behalf of the city of Clarksburg, W. Va., and in behalf of many smaller cities on streams, in the states of Ohio, Indiana, Michigan and Illinois, which were to be drawn upon as sources of public water supply. Mentioning some of these cities where streams have been discussed as sources of water supply are Findlay, Ohio,

Greensville, Ohio;
Eaton, Ohio;
Marion, Ohio;

Zanesville, Ohio;
Bellefontaine, Ohio;
Huntingdon, Indiana;
Lebanon, Indiana;
Greenville, Indiana;
Indianapolis, Indiana;
12321 Aurora, Indiana;
Decatur, Illinois;
Peoria, Illinois;
Oshkosh, Wisconsin;
East Saginaw, Michigan;
Buffalo, New York;
Saratoga Springs, New York;
Chester, Pennsylvania;
Nashville, Tennessee;
Chattanooga, Tennessee;
Birmingham, Alabama;
Mobile, Alabama;
Denver, Colorado;
Trinidad, Colorado;
Pueblo, Colorado.

All of the cities mentioned have submitted either in the course of my work as engineer planning new works or improvement of old works, questions including the availability of different or single sources of water supplies. I say single source especially with reference to towns along the Ohio River where it is rare that any other source can be had than that of the main stream.

12322 Q. In pursuing the work which you have indicated in the foregoing answer to the previous questions what cities have you taken up for consideration as applied to sanitary problems and what methods were pursued by you in your investigations?

A. Aside from purely engineering investigations of water sheds where rivers or ponds have been the sources of public water supply, I have taken up the subject of bacteriology and attempted to qualify myself as an amateur in this line not with a view to pursuing bacteriology as a profession, but with a view to gain information as to the bacteriological condition of water supplies with which as an engineer I would be required to deal. Such work was pursued during leisure time, uninterruptedly from 1894 to 1899. It has been interrupted since coming to Philadelphia, because of lack of time to indulge in the experimental or technical work.

I have also studied the chemistry of water supplies not with a view to chemical analyses but with a view of informing myself as to the true interpretation of chemical analysis of water samples, in connection with my work as engineer in charge of the improvement of the water suppply of Philadelphia.

Q. In connection with the water supply of Philadelphia
12323 are you conducting a laboratory, bacterial and chemical?

A. We do.

Q. Is that laboratory under your direct supervision and direction?

A. Yes sir, it is.

Q. Have you ever investigated any typhoid fever epidemics?

A. Yes sir, several. Two that I now recall, one at Eaton, Ohio, and one in the Cumberland Mountain regions of Kentucky. Both as a part, however, of investigations looking to the improvement of the water supply for the city of Cincinnati. In addition to the investigations noted I have sought information where it has been obtainable in the English or German publications of epidemics that have been reported on in the United States and Europe.

Q. You are acquainted, are you not, with the epidemics from typhoid fever in this country as they appear in the literature such as at Plymouth, Lowell and the others?

A. The records of all these have been read, that is the records of all that I have come in contact with, have been read as the printed documents have been received. It would probably be difficult to recall in detail all the epidemics that have been considered.

12324 Q. Are you acquainted with any epidemics other than those of typhoid fever as they appear in the literature, such as cholera?

A. Yes, the history of the cholera epidemic first in Hamburg and next in the very large compilation of statistics gathered by Dr. Edwin O. Shakespearre of Philadelphia upon cholera in India has been read, studied and noted so far as they seem to contain information that would be of advantage to me as a waterworks engineer.

Q. Have you investigated the sanitary problems as they occurred in Europe?

A. If by investigation is meant an inquiry into the recorded facts as conveyed in public documents, I have.

Q. Have you made a special study of water analysis?

A. I have.

Q. What branch of sanitary science have you given special attention to?

A. Public water supply.

12325 Q. Have you had any experience in the interpretation of chemical analyses of water?

A. I have.

Q. How extensively?

A. Well, really it has gone through the whole period of thirty odd years. The first set of analyses that I can recall from memory were made for the city of Sidney, Ohio, by Professor Chauncey R. Stuntz, analytical chemist of Cincinnati, as early as 1872 or 1873. Of course it must be understood that the sanitary analyses made thirty years ago are not the same as those made today.

Q. In the work here in Philadelphia what have you to do with the interpretation of chemical and bacterial results?

A. It is part of my duty to pass upon the technical investigation of our water samples coming to and from our filters and from them to determine the efficiency of our work of filtration, to do this it is necessary to assign proper values to the results reported from day to day from the technical laboratory.

12326 Q. Have you examined and studied bacterially and chemically the analyses of the water of Lake Michigan, the drainage canal, the Desplaines River, the Illinois River, the Mississippi River and the Missouri River as made by Professors Jordan, Palmer, Burrill and Long, the same being published as reports of Streams Examination which have already been introduced in evidence and the reports of Professor Long appearing in the published health reports of the Board of Health of the State of Illinois, the same having also been introduced in evidence in this case?

A. I have examined the tables of chemical and bacterial determinations contained in the reports mentioned in the question, and have studied them especially with reference to four months during the years 1899 and the corresponding four months during the year 1900.

Q. Are you acquainted with the Chicago River, the drainage canal, the Desplaines, the Illinois and the Mississippi Rivers from Grafton to St. Louis?

A. I am in the main so far as it is represented in published documents and in hydrographic maps published by the United States Government and by the city of Chicago. I have not made a personal examination of the drainage canal

12327 or of the Illinois River excepting of the Illinois River at Peoria during the year 1882 when I was employed on the Peoria water works.

Q. Have you made a special study of bacteriology as applied to water investigations?

A. I have.

Q. Will you distinguish between pathogenic and non-pathogenic bacteria?

A. Pathogenic bacteria are those known or supposed to be the cause of disease in man and other animals. Non-pathogenic bacteria are those that are supposed to be harmless to man and other animals.

Q. What pathogenic bacteria are water borne?

A. The typhoid bacillus, the cholera spirillum, the bacilli coli communis, the bacillus of rabbit septicemia, or the bacillus mesentericus, I think is the term descriptive of it, the proteus vulgaris, the micrococcis of blood poisoning, the staphylococcis pyogenes aureus, the staphylococcus pyogenes albis; there are other pathogenic bacteria found in water which I can not recall from memory.

12328 Q. Are you acquainted with the bacillus prodigiosus?

A. I am.

Q. Have you ever found the bacillus prodigiosus in this country?

A. I think I found it twice in the investigations of the Ohio River water during 1895 and 1896, at least it was differentiated as the bacillus prodigiosus. Comparison was made of its morphology and life history growing on or in different media with a so-called bacillus prodigiosus that I obtained from Dr. Cameron, professor of bacteriology at the Ohio Medical College.

Q. Have you made any special study of the typhoid germ as related to water supply?

A. I have within the limitations of my opportunities.

Q. Is it related to the colon bacillus and if so in what way?

A. It comes into a water supply from the same source as the colon bacillus and resembles the colon bacillus in a number of respects having very nearly the same size when examined under the microscope and having many other qualities quite like the colon bacillus. There are some distinct differences however. The typhoid organism is motile when examined,
12329 while the colon bacillus is nonmotile. Flagella can be developed by staining on the typhoid bacillus, while flagella are not developed on the colon bacillus. Its capacity to resist an acid media is about the same as that of the colon bacillus.

Q. Have you made any experiments upon the longevity of the typhoid bacillus?

A. I did several years ago. In 1895, in sterilized Ohio River water and in unsterilized Ohio River water. These tests on sterilized river water indicated that the typhoid organism would grow without apparent reduction of virility for 60 days. A test made 90 days after the flask had been inoculated with the typhoid organisms failed to reveal its presence and I am unable to state at what time between 60 and 90 days it perished.

The tests made in unsterilized Ohio River water gave negative results. I was never able to find it after the inoculation of the flask of water. I ascribed this not to the nonexistence of the organism some time after the inoculation, but to my inability to demonstrate it on the gelatine plates or to isolate
12330 it on the gelatine plates.

Q. Have you made any other experiments upon the longevity of typhoid bacillus?

A. I have in connection with the work now going on in Philadelphia. Two years ago last fall with a view to determining what, if any, influence the amount of chlorine in the Delaware River might have on the longevity of this organism, at that time I outlined plans that were subsequently put into effect by Mr. Copeland, bacteriologist in charge of the technical laboratory, to show how long the typhoid organism and the colon bacillus would live in unsterilized. Delaware River water with the quantities of chlorine varying from 25 parts per 1,000,000 to 300 parts per 1,000,000 and this test which extended over a number of days, in fact over a number of weeks, revealed the fact that the amount of salt in the Delaware River water had little or no influence upon the longevity of the organism and that its life history was limited to from 5 to 8 days under the most favorable conditions. It also revealed the fact that the colon bacillus would live longer in the unsterilized Delaware River water with the different degrees of salt than would the typhoid organism. 12331

Q. What is the character of the Delaware River water and its sanitary qualities?

A. The Delaware River water is a sewage polluted water which receives the sewage of Trenton, Burlington, Bristol and other towns on the river below Trenton, the sewage thrown into the river from Easton and other towns on the Lehigh River, and the sewage of Phillipsburg, in New Jersey, and from other towns above Phillipsburg as far north as the Delaware Water Gap. It is known to be a distinctly sewage polluted stream below Trenton and the investigation mentioned in my answer to the previous question was with a view to determine what, if any, influence the increased chlorine in the water at the Torresdale Filtration station would have on the typhoid fever germs that might come into the water from points north of our point of intake, which is located about ten miles up stream from the Market Street Wharf.

Q. How were the chlorine tests made?

12332 A. By adding to the normal water common salt until the chlorine was increased first to 25, then to 50 then to

75, then to 100, then to 200 and then to 300 parts per 1,000,000 of water.

Q. Why was it that you made this experiment with chlorine?

A. Because of the probability of an increase of chlorine content in the water to 50 parts per 1,000,000 at a time when the city of Philadelphia is drawing 350,000,000 gallons of water per day from the Delaware River at Torresdale and when the stream flow is at the lowest recorded flow for that river. The excess of chlorine at that time being due to the influence of tidal water coming up the river from Delaware Bay.

Q. What is the population of the towns sewering into the Delaware River and also what is the size of the Delaware River as to volume of flow?

A. I have not made a definite statement of the population of the towns, but what I have made is a statement of the total population gathered on the Delaware watershed exclu-
12333 sive of the Schuylkill.

MR. JEFFRIES: Does that include both rural and urban populations?

A. It is the total population excluding all population collected on the Schuylkill watershed. In my answer of course I would like to correct my figures which are approximate only. I should say that the polluting population from sewered urban centers above the point of intake at Torresdale is about 200,000. I will give the exact figures later on.

Q. What is the size of the Delaware river as measured in volume of flow?

A. In considering the Delaware river and so in considering any river as a source of water supply the lowest stream flow is usually taken into account. Very little or no thought is given to flood volumes or even to mean flow. The lowest recorded flow of the Delaware river is about 1,000,000,000 gallons in 24 hours. The lowest gaugings which I have been able to obtain during the past four years from the station established at Trenton give the lowest stream flow at over two thousand million
12334 gallons per day of 24 hours.

Q. In the making of the experiment which you have detailed state how this experiment was made?

A. The experiment on the stream flow

Q. On the typhoid bacilli?

A. This experiment was made by taking flasks of the Delaware river water from our point of collection at Torresdale testing station and inoculating one of such flasks with a culture of the typhoid fever organism obtained from the health bureau; inoculating another flask with the colon bacillus obtained from fresh feces and carrying one or more flasks as a control in order to compare from time to time the normal water bacteria with the bacteria growing in the flasks which were charged with varying rates of chlorine from 25 parts per million to 300 parts per million. Each test for the longevity of the typhoid bacillus and for the longevity of the colon bacillus was made on eight different flasks including the control flask.

Q. What was the control flask?

12335 A. That contained water with no chlorine whatever.

Q. Was that seeded with typhoid fever germs?

A. In the same manner as the other flasks.

Q. Have you prepared a table showing the results of the experiments to determine the longevity of the bacillus typhosus which you have just recounted in evidence?

A. I have.

Q. Will you produce the table and make the same a part of your testimony?

A. The tables are as follows:

12336

Table showing Results of Experiments to determine the Longevity of B. typhi abdominalis in Sterilized Raw Water of Schuylkill and Delaware Rivers under Various Conditions of Chlorine Content.—Spring Garden Testing Station, Spring Garden Waterworks, Philadelphia, Pa.

Numbers given are Bacteria per Cubic Centimeter.

Number of Test.	Date of Inoculation of Test Flasks.	Average Temperature during Experiment.		Est. Organic Matter introduced into Test Flasks in Parts per Million.	Kind of Water.	Chlorine added to Water in Parts per Million.	Numbers of B. typhi abdominalis in Test Flasks after incubating at given Temperatures for Periods in Days as follows:—									Temperature of Incubation of Plates.	Kind of Medium.	Number of days of Incubation.
		Test Flasks.	Schuylkill Water at Entrance to Bld'g.				0	1	2	3	5	8	12	14	22

12338 Q. Will you state what the tables show that you have just introduced in evidence?

A. One of these tables contains a caption as follows: "Table showing results of experiments to determine the longevity of B. typhi abdominalis in sterilized raw water of Schuylkill and Delaware rivers under various conditions of chlorine contents."

The other table contains caption as follows: "Table showing results of experiments to determine the longevity of B. coli communis in sterilized raw river water of Schuylkill and Delaware rivers under various conditions of chlorine content."

Q. Will you state what the tables show that you have just introduced in evidence?

A. The first table shows the results of test number 4, typhoid fever organism conducted October 7, 1901, the temperature at which the test flask was maintained in the incubator, the chlorine added to the water in parts per million, and the number of typhoid fever organisms found on the plates for various times from the time of inoculation to the third or eighth day of the test. It also shows the kind of medium used in
12339 making the test, and the number of days of incubation before the first test for numbers was made.

The test number 4 in the first column of tables shows that the typhoid organism rapidly diminished in numbers from the day of inoculation to the third day of the test.

Test number 5, made on the 16th day of October, shows that there was a rapid diminution of numbers on the agar plates from the day of inoculation until the fifth day of the tests, but a small number was found on the eighth day of the tests.

I would like to state that this test was made not for the purpose of showing the longevity of the organisms but rather to show what, if any, influence varying quantities of chlorine content would have upon the growth of the organisms in Delaware river water.

Q. What does the second chart show?

A. The second table shows the same numbers as those given above with reference to the bacillus coli communis, the test being made upon the same day and in the same manner and with the same kind of water for the latter organism as for the typhoid fever organism and this table reveals the fact that the 12340 colon bacillus will live longer in the Delaware river water with varying degrees of chlorine content than does the typhoid fever organism.

Q. What conclusions did you arrive at from the results of this test as to the effect of chlorine upon the longevity of the typhoid bacilli?

A. Briefly it seemed to have no effect. The purpose of this test was to determine whether the increased chlorine which is anticipated when the draft of water from the river at Torresdale becomes large, due to low stream flow and the influence of tidal water coming up the river from Delaware Bay. As to first whether the increased chlorine would permit the growth of the typhoid organism in river water. Next whether it was calculated to increase its longevity both of which factors were under consideration with reference to the establishment of the filter station at Torresdale at the time these tests were made in 1901.

Q. Aside from the question of the longevity of the typhoid germ as affected with the presence of chlorine does this 12341 test afford you any information or a fact upon which to base and predicate an opinion as to the life or longevity of a typhoid in polluted river water?

A. Yes sir, it does. In the absence of information to the contrary I should assume the longevity of the typhoid organism in lake or river water where the sewage pollution was no less than that of the Delaware river at Torresdale would be substantialy the same as that found here. I give this opinion in view of the fact that the temperature of incubation doubtless would be the same for unsterilized or sterilized water taken from any other suspected source of water supply, and in the case of special information collected at some other point from some other stream or source of water supply I should be governed in expressing an opinion on the longevity of the typhoid organism in unsterilized polluted river or lake water by the results of the tests made on the Delaware river water at the Torresdale testing station and the results of tests also made on the Schuylkill river water at the Spring Garden testing station. The tests with the sterilized Schuylkill water being given in the first line of each of the tables, and the next seven are sterilized Delaware river water.

12342 Q. Was this test made on the sterilized or unsterilized water?

A. On sterilized water.

Q. Why was sterilized water selected?

A. Because it was thought to be more favorable to the growth of the organism than unsterilized water, and because it eliminated the danger of our failure to detect the typhoid organisms after a few days of growth, no other organism growing in the water excepting that due to the inoculation of the test flasks.

Q. Would this experiment made on sterilized water furnish you with a basis for an opinion as to the longevity of the typhoid germ in the raw water of these rivers?

A. It would because such data as has come under my observation indicates that the typhoid organism or any specific water bacteria will live longest in sterilized water, due to the fact that sterilization does not remove the food material and possibly increases its availability as food for the bacteria and such food material is consumed only by the organism with which the experiment is being made.

Q. What is your opinion based upon the experiment which you have just introduced in evidence as to the longevity of the typhoid fever germ in the raw waters of these two rivers

12343 at a point where the experiment was made?

A. I should feel safe in expressing an opinion that the organism would certainly not live longer in the unsterilized than it did in the sterilized water, and probably would have a shorter life history. The greatest length of time that a typhoid fever organism lived as shown by the tables is 8 days. I should anticipate that its life in the unsterilized water would certainly be no longer than 8 days and probably less than 8 days, by reason of the facts stated in answer to a previous question with reference to the influence of sterilized water on the life history of the organism with which it may be inoculated.

Q. Are the conditions of laboratory experiments more or less favorable than the conditions in nature for the longevity of the typhoid bacillus in your opinion?

A. I regard the laboratory test usually made and certainly

all that I have made or caused to be made as more favorable to the growth of the typhoid organism than it would be in the normal water with which the experiment was being conducted, as the desire is to show the greatest possible longevity
12344 under the conditions of the test. This is brought about by maintaining a constant temperature of the flasks in which incubation is being carried on and by observing all other conditions conducive to the maintenance of life of the organism.

Q. From your knowledge of this organism what is your opinion as to the longevity of the typhoid bacillus in ordinary river waters which are receiving sewage from urban centers?

A. I should put the life of the typhoid organism in a sewage polluted river water under normal conditions which prevails with the majority of the rivers of the United States drawn on as the sources of public water supply as from 5 to 8 days. I am now referring to the typhoid organism that would come in from a definite point. That organism would probably be not found in the water at the end of five to eight days.

MR. JEFFRIES: Does that now apply to all waters and all characters and conditions or are you referring now to the Schuylkill river?

A. It would be rivers where the normal temperatures were about like those of Philadelphia. I would not like to apply that to the St. Lawrence river for example because I am not quite sure about it, but I think the colder the stream the longer
12345 the organism would live and the warmer the stream the quicker it would perish.

Q. Now, with reference to the degree of pollution, would that have any effect?

A. Yes, it would. But I am assuming as a general proposition that the rivers, when they are the source of public supply as the Delaware, the Schuylkill, the Merrimack, the Hudson, the Missouri and the Mississippi at points of intake for large cities are not largely different with reference to sewage pollution, that is it is more intense in some cases than in others, but nevertheless there is a distinctive sewage pollution in all those streams that would have some modifying influence on the longevity of the organism.

MR. TODD: Would the Illinois river be found in the class of rivers which you have referred to in your previous answer?

A. It would.

Q. To be specific, what is your opinion as to the longevity of the typhoid fever germ in the waters of the drainage canal, the Desplaines and the Illinois rivers?

MR. JEFFRIES: I object to the question for the reason
12346 that the witness has not shown that he possesses proper
information as to the extent of pollution in the Illinois river and the stream flow of that river.

MR. TODD: In reply to counsel will state that the witness has stated that he has familiarized himself with the chemical and bacterial data already introduced in evidence and counsel submits that that information is sufficient upon which to predicate an opinion. The conclusions from these different analytical data will be developed at a later period in the examination.

Q. To be specific, what is your opinion as to the longevity of the typhoid fever germ in the water of the drainage canal, the Desplaines and the Illinois rivers, based upon all the knowledge which you have as to the longevity of the typhoid fever germs in similar waters?

A. From such information as I have of the bacteriological and chemical contents of the Illinois river as disclosed in the volume entitled Streams Examination, prepared by the Sanitary District of Chicago, and of the physical conditions with reference to slope, of their being slack water pools formed in the river at
different points, I should not anticipate a greater longe-
12347 vity of the typhoid organisms in the waters of the Illi-
nois river than I have found in the waters of the Schuylkill and Delaware rivers.

Q. Are there any other experiments aside from those you have detailed which you know of or have made yourself touching upon the longevity of the typhoid bacillus as compared with the life of the other bacteria

A. I have a table which I have made to determine the longevity and follow the life history of the typhoid organism in sterilized and unsterilized river waters.

Q. Are you acquainted with the physical conditions of the drainage canal, the Desplaines river and the Illinois river and the Mississippi river from Chicago to St. Louis?

A. I am so far as information can be obtained from the publications of the hydrographic journals of the Coast Survey,

which has undertaken to show in detail all physical and hydrographic conditions affecting the principal streams of the United States, and which I have accepted as indicating correct conditions as far as they could have been stated with reference to the principal streams of this country. My personal
12348 knowledge of the Illinois river is limited to my association several years ago for a short time with the water works of Peoria, Illinois, when that city was drawing its water from the so-called Lake Peoria.

Q. Assuming that there are four dams in the Illinois river, one at Henry, one at Copperas Creek, one at LaGrange and one at Kampsville, what effect do those dams have upon the problem of sedimentation?

A. The dams, whatever the number may be in the Illinois river, particularly in view of the flat slope of the stream bed will create pools corresponding in number to the dams in which sedimentation is bound to take place. Each of these pools acts very like a sedimentation basin when operated upon the so-called continuous plan, that is to say a sedimentation basin where the water is pumped in at one end and removed at the rate from some other end or point, usually at the opposite end of said basins. I regard the 25 or 26 pools formed in the Schuylkill river between Fairmont dam and Port Clinton, a distance of about 96 miles from Fairmont dam, as active auxiliaries in the purification of the polluted Schuylkill water and I believe that if those dams were removed and only Flat Rock dam at
12349 the Shawmont pumping station and the Fairmont dam at the Fairmont pumping station remained, that the condition of the water coming through our intakes at Shawmont, Belmont, Queen Lane, Spring Garden and Fairmont would be worse that it is now, and the same condition with reference to sedimentation would apply by the maintenance of the dams in the Illinois river, but with greater force by reason of the flatter slope of the stream and the longer the pools formed by each of the dams.

Q. Are you acquainted with the conditions in the Illinois river in regard to its banks as to whether the banks are high or low?

A. I am acquainted with the general topography of the

State of Illinois and acquainted with the channel conditions of the Illinois river at and in the neighborhood of Peoria, and I know that as a rule the banks are low.

Q. What effect do the flood waters in the Illinois river have upon the bottom lands lying in the Illinois river valley?

A. Flood conditions should take the river out of its channel in many places and spread the water over the bottom land, largely widening the channel at such points.

12350 Q. How is the sedimentation in the Illinois river affected by high stages of water overflowing the banks?

A. The percentage of sedimentation would probably be increased by the river rising to such a stage as would overflow the bottom lands, producing over such lands a shallow depth of water moving at a low velocity, both of which would favor precipitation of suspended solids.

Q. Assume that there are in the neighborhood of 400,000 acres of land inundated and subject to overflow in the Illinois river, what effect would this overflowed area have upon sedimentation?

A. It would be to increase the rate of sedimentation during that time when the stream was out of its banks for the reason given in the answer to the previous question.

Q. Will bacteria respond to the law of gravity in the water of a running stream?

A. The specific gravity of bacteria is slightly greater than that of water and in quiescent water bacteria will slowly settle to the bottom. The rate of flow of the water would determine the time required for the bacteria to settle. However, it is known that in a turbid stream carrying considerable silt, sand and other solid matter that there is an engulfing or en-
12351 veloping, rather, of the bacteria by the suspended matter which, when it precipitates, carries the bacteria with it, and in a stream carrying considerable soil, washed from its drainage area, the precipitation of the bacteria is rapid, and is supposed to be due to the agglomeration of bacteria, solids and other suspended matter in masses until a gravity is acquired that will carry it to the bottom of the stream.

Q. Could sufficient water from Lake Michigan—assume that the maximum flow through the drainage canal is 800,000 cubic feet per minute—be carried through the drainage canal into the Desplaines and Illinois rivers so as to create a condition or permit a clearness to such an extent as to preclude the operation of sedimentation in the Illinois river?

A. I do not think that the quantity of water mentioned would impede sedimentation, but it might diminish the rate at which sedimentation would occur during stream flow.

Q. Assume that the entire sewage from the city of Chicago should be diverted into the drainage canal and that 800,000 cubic feet of water per minute from Lake Michigan should pass over the Bear Trap dam, would that amount of pollution be
12352 sufficient if it reached the Illinois river to make the Chicago sewage separate matter under the circumstances in the Desplaines and Illinois river so as to prevent the operation of sedimentation?

A. No, it would not. It might modify the rate of sedimentation, but it would not prevent it.

Q. What sanitary significance does dilution have in considering the problem of self-purification of streams?

A. Dilution of a sewage polluted stream means or should mean dilution with purer water than that flowing in the stream. It operates in two ways, first, self-purification, in a mechanical way by increasing the volume of flow in the main stream and reducing the percentage of pollution; next, to increase the rate of oxidation of organic matter by adding to the polluted water a water higher in dissolved oxygen, and it is probable that with reasonable limitations the addition to a sewage polluted stream of a stream of purer water high in dissolved oxygen, would facilitate the oxidation of organic matter.

Q. Is the danger of infection really diminished by dilu-
12353 tion?

A. Yes, it is.

Q. In what way?

A. By reducing the percentage degree of pollution when referred to the total volume of water flowing. Dilution of the sewage polluted water would act exactly in the same manner as the dilution of a poison. The degree of pollution finally may be reduced to such a small amount as to eliminate all danger.

State of Illinois and acquainted with the channel conditions of the Illinois river at and in the neighborhood of Peoria, and I know that as a rule the banks are low.

Q. What effect do the flood waters in the Illinois river have upon the bottom lands lying in the Illinois river valley?

A. Flood conditions should take the river out of its channel in many places and spread the water over the bottom land, largely widening the channel at such points.

12350 Q. How is the sedimentation in the Illinois river affected by high stages of water overflowing the banks?

A. The percentage of sedimentation would probably be increased by the river rising to such a stage as would overflow the bottom lands, producing over such lands a shallow depth of water moving at a low velocity, both of which would favor precipitation of suspended solids.

Q. Assume that there are in the neighborhood of 400,000 acres of land inundated and subject to overflow in the Illinois river, what effect would this overflowed area have upon sedimentation?

A. It would be to increase the rate of sedimentation during that time when the stream was out of its banks for the reason given in the answer to the previous question.

Q. Will bacteria respond to the law of gravity in the water of a running stream?

A. The specific gravity of bacteria is slightly greater than that of water and in quiescent water bacteria will slowly settle to the bottom. The rate of flow of the water would determine the time required for the bacteria to settle. However, it is known that in a turbid stream carrying considerable silt, sand and other solid matter that there is an engulfing or en-

12351 veloping, rather, of the bacteria by the suspended matter which, when it precipitates, carries the bacteria with it, and in a stream carrying considerable soil, washed from its drainage area, the precipitation of the bacteria is rapid, and is supposed to be due to the agglomeration of bacteria, solids and other suspended matter in masses until a gravity is acquired that will carry it to the bottom of the stream.

Q. Could sufficient water from Lake Michigan—assume that the maximum flow through the drainage canal is 800,000 cubic feet per minute—be carried through the drainage canal into the Desplaines and Illinois rivers so as to create a condition or permit a clearness to such an extent as to preclude the operation of sedimentation in the Illinois river?

A. I do not think that the quantity of water mentioned would impede sedimentation, but it might diminish the rate at which sedimentation would occur during stream flow.

Q. Assume that the entire sewage from the city of Chicago should be diverted into the drainage canal and that 800,000 cubic feet of water per minute from Lake Michigan should pass over the Bear Trap dam, would that amount of pollution be 12352 sufficient if it reached the Illinois river to make the Chicago sewage separate matter under the circumstances in the Desplaines and Illinois river so as to prevent the operation of sedimentation?

A. No, it would not. It might modify the rate of sedimentation, but it would not prevent it.

Q. What sanitary significance does dilution have in considering the problem of self-purification of streams?

A. Dilution of a sewage polluted stream means or should mean dilution with purer water than that flowing in the stream. It operates in two ways, first, self-purification, in a mechanical way by increasing the volume of flow in the main stream and reducing the percentage of pollution; next, to increase the rate of oxidation of organic matter by adding to the polluted water a water higher in dissolved oxygen, and it is probable that with reasonable limitations the addition to a sewage polluted stream of a stream of purer water high in dissolved oxygen, would facilitate the oxidation of organic matter.

Q. Is the danger of infection really diminished by dilu-
12353 tion?

A. Yes, it is.

Q. In what way?

A. By reducing the percentage degree of pollution when referred to the total volume of water flowing. Dilution of the sewage polluted water would act exactly in the same manner as the dilution of a poison. The degree of pollution finally may be reduced to such a small amount as to eliminate all danger.

Q. Is it a fact that the greater the dilution of sewage the less danger from infection?

A. It is.

Q. What effect does the dilution of the Chicago sewage with the water of Lake Michigan have upon the sanitary quality of the water of the Illinois river?

A. The water drawn from Lake Michigan is probably purer than the water normally flowing in the Illinois river, and the addition of water from Lake Michigan should improve the quality of the water flowing in the Illinois river in proportion
12354 to the relative volumes of original stream flow and flow derived from Lake Michigan.

Q. Is the addition of the Lake Michigan water to the sewage of Chicago a detriment or a benefit to the sanitary condition of the Illinois river considered from the standpoint of dilution alone?

A. The water flowing into the Illinois river from Lake Michigan should be regarded as a benefit to the Illinois river.

Q. Is the addition of Lake Michigan water to the sewage of Chicago a detriment or a benefit to the sanitary condition of the Illinois river considered from the standpoint of the chemical and bacterial changes taking place?

A. Basing an opinion upon the tables giving the chemical and bacteriological determinations for the months of June, July, August and September, 1899, and for the same months for the year 1900, it does not appear that the addition of the sewage of Chicago to the Illinois river is a detriment. Generally speaking a comparison of the data for the four months of the two years mentioned, the condition of the river below the city of Peoria is better for 1900 than it was for 1899. The nitrites are de-
12355 creased, considering the river below Peoria, and the nitrates increased, showing self purification going on in a greater degree during the year 1900 than during the year 1899. In giving this answer some account must be taken of the difference of stream flow for the two years, but notwithstanding that the stream flow, according to the evidence of Mr. Jacob A. Harmon, was greater for 1900 than for 1899, I still think the indications are that the chemical conditions or at least some chemical conditions indicate that self purification is better for the latter year, and having no better data before me than that quoted in

the answer or that mentioned in the question it does not appear that the addition of the sewage in Chicago has injured the quality of the water of the Illinois river south of Peoria.

Q. If a sufficient volume of Lake Michigan water should be added to the sewage of Chicago so as to cause an elevation of the waters in the Desplaines and Illinois rivers, what effect would this increased volume of water have upon the means of sedimentation in the Illinois river?

12356 MR. JEFFRIES: I object to the question for the reason that it is indefinite.

A. The addition of water to the Illinois river from Lake Michigan would increase the current and increase, to some extent, the time required for sedimentation. If the increased volume of water was such as to overflow the banks it might upon the whole have the opposite effect by reason of the large degree of sedimentation that would take place outside of the defined channel of the river on the bottom lands. If, however, it should be shown that the mean velocity of the stream was not materially increased by the addition of water from Lake Michigan it would probably have no marked effect on the rate of sedimentation. The chief factor that would govern in this case would be the mean velocity of the flow of river before and after the addition of water from the lake.

MR. TODD: Q. How do the physical conditions of the Illinois river compare with the other rivers of the country for the purposes of purification and sedimentation?

A. The sedimentation and oxidation of organic matter during stream flow is favored by a low channel and surface slope of the stream. Self purification of a flowing stream would
12357 depend upon time and distance and in two cases where
the distances were the same, but the time of flow for one, between the upper station and the lower station on such a stream would be greater than for the other, the degree of self purification should be greatest with that stream where the time of flow would be greatest, or where the number of hours and days that pass between the upper and lower stations would be the greatest. There is probably very little self purification in rapidly flowing mountain streams, and a very large degree of self purifictaion in streams of slow current in the low lands.

Q. From your knowledge of the physical conditions that obtain along the Illinois river as well as the inspection of the results of the analyses of water, both chemical and bacterial, what effect in your opinion, if any, does the sewage from Chicago discharged into the drainage canal have upon the waters of the Mississippi river, as the same passes along the shore of the State of Missouri?

A. Basing an opinion upon the technical investigations that have been made of the water of the Illinois river at Grafton during the four selected months of 1899 and the four
12358 corresponding months of 1900 it does not appear that the sewage of Chicago has materially changed the conditions, and such changes as are shown would indicate from a chemical point of view an improvement in the quality of the water at Grafton, since the opening of the drainage canal.

Q. What is your opinion as to whether any pollution dangerous to public health entering the drainage canal from the sewers of Chicago reaches as far down the Illinois river as the town of Grafton?

A. Basing an opinion on the technical data contained in the book entitled Streams Examination which has been referred to before in my testimony, there is nothing to indicate that the danger to public health has been increased since the opening of the drainage canal. In making this statement I wish it understood that I do not believe that the water flowing in the Illinois river at Grafton before the opening of the drainage canal was fit for drinking and some other domestic uses, and my answer must be construed as showing only that the conditions are no worse during the months of 1900 which I have under consideration than they were during the corresponding months of
12359 1899 prior to the opening of the canal.

Q. What evidence have you that would justify the conclusions just expressed in your previous answer?

A. I have a compilation of chemical and bacterial data taken from the tables prepared by the chemical and bacteriological experts acting in behalf of the city of Chicago as they appear in the book entitled Streams Examination, previously referred to.

(Let the record show that when the witness refers to the book known as Streams Examination he also includes Professor Long's chemical analyses as shown in the report of the Illinois

State Board of Health, unless such analyses are eliminated specifically by the witness in his answer; all of which have been introduced in evidence and the witness says he has examined).

A. The figures which I now refer to are taken entirely from the book entitled Streams Examination and they show the following numbers of the percentages of decrease or increase for the bacteria or suspended matter or total solids or total oxygen consumed, nitrites and nitrates and finally chlorine, which tables purport to be made as above indicated, and are as follows:

12366 Q. What do these tables show?

A. This table shows in the following order:

1. An increase in the bacterial content of the water from Havana, Illinois, to Grafton.

A decrease in the suspended matter from Wesley City to about one-fourth the distance from the Missouri shore into the Mississippi river, at Chain of Rocks.

An increase in the total solids from Chicago to Grafton.

A reduction in the total solids from the Mississippi river at Grafton to one-fourth the distance from the Missouri shore, at Chain of Rocks.

An increase in the total solids from the Missouri shore of the Mississippi river to the Missouri shore at the St. Louis water works.

A reduction in the total solids of the Missouri river at West Alton.

It shows, with two exceptions, a material reduction in the total oxygen consumed, which is, in my opinion, significant as indicating self purification by natural processes during stream flow past the thirty-two stations named in the table.

Number 18, Chandlersville, Sangamon river, shows an
12367 increase in the total oxygen consumed.

Number 32, the Missouri river at West Alton, and all the other stations from the Illinois and Michigan canal at Bridgeport, down to the Missouri shore of the Mississippi river at the St. Louis waterworks, show a reduction.

Considering the nitrates and nitrites which in my opinion are always significant factors in showing changes taking place in the quality of polluted waters, and which where purification is being effected by sedimentation or filtration or any other of the known practical means not including sterilization by heat, the nitrites should diminish as the water is reduced in sewage pollution and the nitrates should increase.

Considering the table before me with the exception of four stations, namely, the Desplaines river at Joliet, the Kankakee river at Bloomington, the Illinois river at Morris and the Sangamon river at Chandlersville, the nitrites are largely decreased, and omitting nine stations, namely, the Illinois and Michigan canal at Bridgeport, the same canal at Lockport, the Desplaines river at Lockport, the Fox river at Ottawa, the Illinois river at
Ottawa, the Illinois and Michigan canal at LaSalle, the
12368 Illinois river at LaSalle, the same river at Henry and
the same river at Averyville, there is everywhere else a marked increase in the nitrates. If I was applying the information contained in the sheet showing the nitrates and nitrites for 1899 and 1900 and the percentages of decrease and increase to the work of filtration I should have no hesitation in claiming the same degree of purification by the filters as is here shown by self purification or sedimentation in the channel of the river. Referring to the tables showing the chlorine this has increased for all stations from the Illinois river at Kampsville down to the Missouri river at West Alton excepting the intake of the St. Louis water in the Mississippi river where the tables show a diminution of chlorine. Taking all the data together and particularly that relating to the total oxygen consumed, and the nitrates and nitrites, I consider that the condition of the water flowing in the stream at Grafton has been improved.

Q. In the tables which you have just introduced, on the first page appears at the head of the column "Station" with consecutive numbers following, with the names of the
12369 places which such consecutive numbers indicate, and in the following tables only the consecutive numbers are indicated. Do these consecutive numbers in the first column of the table indicate the name of the station as are set forth in the first table?

A. They do.

Q. What is your opinion as to whether any infectious matters coming from the sewers of Chicago by way of the drainage canal in a dangerous state reach as far down the Illinois river as the city of Grafton?

A. Basing the opinion upon the technical data collected by others for the purposes of this investigation, I do not think that the sewage of Chicago in its original condition is manifested in the waters of the Illinois river at Grafton.

Q. Upon what do you base this opinion?

A. Chiefly upon the tables containing a record of the determinations of nitrates and nitrites at the 32 stations under consideration.

Q. Would the conditions of low water in the Missouri river at a time when there was high water in the Illinois river be in any way a factor in carrying infected and polluting mat-
12370 ters from the sewers of Chicago to the city of St. Louis?

A. I do not think that it would because the question of high or low water of the Missouri river would have no influence on the amount of water flowing in the channel of the Illinois river at or near Grafton. It might increase the surface slope of the stream, but considering the length of the stream, its flat slope, and the number of dams, it is doubtful if the change in the stages of water in the Missouri river would have much influence upon the flow of the Illinois. It certainly would not have a tendency to increase the current throughout its length.

Q. Professor, from your knowledge of the conditions that obtain along the Illinois river as well as your knowledge of the conditions that obtain in Chicago and the drainage canal, and your knowledge of the water supply of St. Louis, such as is to be had from the intake tower at the chain of rocks, and all other sources of knowledge which you may possess, what effect does the sewage from Chicago have upon the water supply of the city of St. Louis or upon the water of the Mississippi river as the same passes along the State of Missouri?

12371 MR. JEFFRIES: I object to the question as a repetition.

A. Considering the technical data already referred to in previous answers and contained in the book entitled Streams Examination and considering the relative drainage area of the Illinois river and the Mississippi river above St. Louis and of the Missouri river, I do not think that any marked effect would be felt in the combined waters of the three rivers by reason of the combined discharge of sewage and Lake Michigan water into the head waters of the Illinois river at Joliet.

Q. Why is it that the typhoid bacillus will not live as long in polluted water as in pure water?

A. Because of the presence in much larger numbers of the stronger bacteria of putrefaction and fermentation which find a normal habitat in polluted water.

Q. How does the typhoid bacillus behave in moist soil?

A. I have no information upon that matter that has come to me in a way to be conclusive and I can not answer the question for that reason.

Q. What is your opinion as to whether a typhoid bacillus will live longer in the sediment of a polluted stream than
12372 it would in the water of the same stream?

A. I have no data upon that proposition either. I should think that the organism would perish more quickly in the sediment of the stream where the destruction of organic matter is actively going on by the agency of the putrefactive bacteria than it would in the water above such sediment. Proof along this line, however, I am not able to offer.

Adjourned until 2:00 p. m., same day, March 28, 1904.

12373 2:00 p. m., Monday March 28, 1904.

Met pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

JOHN W. HILL

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

Q. What is your opinion, based upon all the knowledge that you possess, as to whether a typhoid bacillus coming from the sewers of Chicago and entering the drainage canal could survive the journey from Chicago to St. Louis, a distance of 357 miles, and be a danger and a menace to the inhabitants of the city of St. Louis and the inhabitants of Missouri, using the water of the Mississippi river for drinking and domestic purposes?

A. In the light of such information as I have upon the longevity of the typhoid bacillus in unsterilized waters and of the special knowledge with reference to the conditions subsisting along the Illinois river I should not expect a typhoid
12374 organism introduced into the Illinois river together with the sewage of Chicago and Joliet to pass the entire length of the stream. Upon the contrary I should expect it to perish somewhere in transit and probably before it reached the city of Peoria, and the reason for this opinion is based upon the evident rate of reduction of organic matter in the river between the point of discharge into the canal and the city of Peoria, the typhoid bacillus like other bacteria being a part of this organic matter.

Q. Are you acquainted with the settling basins of the city of St. Louis?

A. I am as they are described in the reports of the water commissioners of St. Louis which reports I have had on file for the past twenty years: I have never personally visited the settling basins that form a part of the St. Louis water works. My information with reference to those is refreshed by reading the report of the Commission of Hydraulic Engineers upon the subject of new water supply for the city of St. Louis, which report was published about two years ago.

Q. How long have you been acquainted with the water
12375 supply of the city of St. Louis?

A. By means of the annual reports of the water commissioners for twenty years and taking into consideration the report of Mr. J. T. Kirkwood, made in 1866 or 1867, which was the basis for the general reorganization of the water works of

St. Louis for a period of thirty-six or thirty-seven years, because Kirkwood's work was one of the early works that I studied in connection with public water supplies.

Q. Who was Mr. Kirkwood to whom you refer?

A. Mr. Kirkwood was one of the most eminent hydraulic or water works engineers in the United States, and in 1865 or 1866 was employed by the city of St. Louis to develop plans for the general improvement of the water supply.

Q. Did you know Mr. Kirkwood?

A. I met him once some twenty years or more ago in New York.

Q. Is that the Mr. Kirkwood that visited Europe and made a report on filtration to the city of St. Louis?

A. The same.

Q. And that report has been published?

A. Yes sir. He made what was the earliest and for
12376 many years considered as the most elaborate report on
the filtration works of Europe, that was printed in the English language.

Q. Do you regard the settling basins at St. Louis as they are at present constituted a complete guarantee against infection coming from the waters of the Mississippi river?

MR. JEFFRIES: I object to the question on the ground that it is immaterial.

A. I do not.

MR. TODD: Q. For what reason?

A. Because it is not possible with such limited sedimentation as can be carried on in the St. Louis reservoirs to so purify an ordinarily polluted water as to fit it for domestic uses. Settling basins such as would be required to eliminate 99 or 99½ per cent. of the bacteria and bring about a corresponding reduction of turbidity, things that are desired in potable water would be of such enormous size as to make them prohibitory by reason of the cost and by reason of the area occupied.

Q. Are you acquainted with the settling basins in the city of Covington, Kentucky?

A. I am.

12377 Q. What acquaintance have you with those settling
basins?

A. I was familiar with the construction at the time they

were being built by reason of temporary employment by the contractors and by reason of further connection with the suit brought by the contractors, Casparis & Co., against the trustees of the Covington Reservoir, for alleged extras in connection with the work of construction. Later on I renewed my acquaintance with these works in connection with the plans for the improvement of the water supply of Cincinnati at which time samples were taken from the Covington reservoirs to determine how much, if any, purification was going on by reason of long sedimentation. At that time the two distributing basins carried about thirty days' supply, that is to say when operated upon the continuous sedimentation plan it would take about thirty days to empty the reservoirs or rather to discharge the original volume of water and have it replaced with unsedimented water pumped from the Ohio river. The result of those investigations is recorded in the report of the Engineering Commission of the city of Cincinnati published March, 1896. And as I now recall upon some occasions the bacterial tests of the water in
12378 Covington reservoirs compared with the tests of the water in the river flowing past the intake of the Covington pumping station, revealed at times a reduction of the bacteria by as much as 97 per cent. I think the average of the tests that were made (perhaps a dozen or more during the months of January, February and March, 1896), indicated more than 90 per cent. bacterial reduction by simple sedimentation for thirty days.

Q. Where the settling basins such as existed at Covington, Kentucky, held a sufficient amount of water to supply the city of Covington for a period of thirty days and as the water was taken out for domestic uses is immediately supplied from the open river and typhoid fever should prevail among the people of Covington using such water what is your opinion as to whether such a condition of typhoid fever existing in Covington, Kentucky, justifies the assumption that because the basins hold a supply for thirty days that the typhoid bacillus will live in that water for such a period?

A. I do not think that it does justify such an assumption. The circumstances with reference to Covington and the
12379 sister city of Newport, which also has a large sedimentation basin, and the city of Cincinnati is this: a large part

of the population of each of the two smaller cities in Kentucky do business or are otherwise engaged daily in Cincinnati, and from investigations of the typhoid fever rates of the three cities from 1890 to 1896, there is satisfactory evidence to my mind that the larger part of the typhoid in Covington and Newport is chargeable to the Cincinnat water, that is to water that was used by the people who were either attending school or looking after business or doing their shopping in the larger city, and a fair test of the influence of thirty days' sedimentation on the Ohio river water is not made in the daily experience of Covington because of this constant change of population from Covington to Cincinnati every day excepting Sunday. Notwithstanding the conditions which reflect upon the action of the Covington reservoir, the typhoid fever rates are much lower in Covington than they are in Cincinnati.

Q. Have you the typhoid rate of Covington and Cincinnati?

A. I have for the years 1890 to 1896. Quoting the rates 12380 of Cincinnati for the years 1890 to 1896, inclusive, by years they run as follows per 100,000 of population.

1890	67
1891	62
1892	40
1893	43
1894	50
1895	36
1896	48.
	——
Average	49.4

For Covington for the same years and upon the same basis:

1890	43
1891	45
1892	40
1893	27
1894	42
1895	27
1896	32.
	——
Average	36.6

With the exception of the year 1892 the typhoid fever rates
per 100,000 population were always lower in the city of
12381 Covington than in the city of Cincinnati, both taking
water from the Ohio river.

Q. What was the character of the water supply of Cincinnati during this time?

A. In general terms it was bad because at that time and now no attempt had been made at improvement of the quality of the water after it was taken from the river, excepting such as may take place in passing through the Eden Park reservoir which holds ordinarily about one and one-half days supply.

Q. From what you know of the typhoid conditions existing in Covington, Kentucky, what is your opinion as to the validity of attributing the typhoid conditions to the water from the reservoir of the city of Covington?

A. Having investigated the typhoid fever rates at Covington it never occurred to me that it was chargeable to the local water, but that it was chargeable to the very considerable daily consumption of unsedimented water that the people of Covington drunk or some of them drunk in the city of Cincinnati daily. There are other sources of typhoid infection that
must be taken into consideration, namely the drinking of
12382 water during travel of the members of an organized
community, and importing cases which will be charged to
the city of residence. I do not believe that all typhoid in Covington was due to the Cincinnati water, but I do believe a large portion of it was. In Covington also there is considerable drinking water used from old-fashioned dug wells, and it is possible that some of the typhoid may be chargeable to that cause.

Q. What effect do wells have upon the public health as regards typhoid in large cities?

A. It is I believe a common opinion of sanitarians today and it is certainly my opinion that an open well is not a safe source of drinking water in an old and well built up urban community, by reason of the fact that soil in due times will become polluted with the wastes from privy vaults and cess pools and that pathogenic bacteria and perhaps other objectionable matter from such cess pools and vaults may by the ordinary means find a way into the well, and render such water unfit for drinking purposes.

Q. In the interpretation of typhoid statistics of a city what method do you employ?

A. My custom in stating typhoid fever cases and deaths 12383 is to relate the rates to the unit of one hundred thousand population living.

Q. Are you acquainted with the mortality percentage method?

A. Yes sir.

Q. What is your opinion as a sanitarian as to the validity of that method being employed in the interpretation of typhoid statistics?

A. It does not as easily convey to the ordinary mind the true relation of the typhoid fever statistics of the population as the method of relating deaths or case to some unit of population, for example 10,000 to 100,000. For the reason that relating the typhoid fever deaths or cases to the deaths or cases from other causes, if the general mortality rate was low and the typhoid fever rate referred to population unchanged, it will create an impression in the ordinary mind that the typhoid rate had been increased while it had remained unchanged, whereas if the comparison is made on the unit of population whatever that unit may be, the ordinary mind can follow more easily as to whether the typhoid fever rates were increasing or diminishing or maintained at some constant rate.

12384 Q. Is the mortality method regarded as on the whole the most accurate among sanitarians and students of vital statistics in ascertaining typhoid conditions of a given community?

A. I do not think it is. The custom in Germany and England is to state the typhoid fever rates and the rates from other infectious diseases upon some unit of population, occasionally 10,000 and sometimes 100,000.

Q. What are the liabilities of pollution and infection of a river coming from the rural population?

A. The danger of infection is not so great from the rural population as from the established centers of urban population because the opportunities of sewage from the rural population reaching some water course are not so great as in established centers where systems of sewerage are in vogue.

The element of time enters into the probability of infection from rural soures. There is an exception that can be made to that in the case of an epidemic of typhoid fever at Wesleyan University some seven or eight years ago at which time there was an epidemic of typhoid fever among the students of the University which finally was traced to oysters eaten by one of
the college fraternities at their annual banquet. In this
12385 case the infection of the oyster bed was traced to a rural
residence, that of the oyster grower where his wife or daughter or both had typhoid fever and where the little drain that carried the sewage from the privy emptied into a neighboring creek and in that creek at some distance below the mouth of the drain was located the oyster growers bed. This is one authentic case of rural infection of typhoid, and is quite recent.

Q. Are not the Plymouth and Lowell epidemics of rural origin?

A. The Plymouth is distinctly rural, because the residence of the parents of the young man who was supposed to be the cause of the Plymouth epidemic was isolated on the water shed of the impounding reservoir that furnished the water supply to Plymouth. My recollection is that it was a suburban factory or a small establishment on a little creek emptying into the Merrimack river below Lowell that furnished the foundation for the Lowell epidemic some thirteen or fourteen years ago. The details of the Lowell epidemic I cannot recall quite so well, but it is reported in detail in the reports of the Massachusetts State Board of Health. I remember, however, the report on it by Professor Sedgwick, and it came either from a small establish-
ment or factory a short distance from the point of en-
12386 trance of the little stream which discharged into the
Merrimack river.

Q. When you consider the question of the condition of typhoid fever in a given community do you regard it as important to note the interval of time elapsing between the infection of a water supply and the drinking of the infectious water by the people?

A. Yes, if the time is known when the water supply is infected due regard is had for the condition between the time of infection and the time of the outbreak of the fever. It is customary to allow as between the time, however, when the infected water is used, and the outbreak of fever a period of at least two weeks.

Q. If upon a water shed where the water is polluted there should be many sources of pollution and infection and typhoid fever should break out in a given community, where would you look for the source of infection?

A. At the nearest possible point of pollution above the source of water intake or above the point of water intake.

Q. Why would you do that?

A. Because the nearer the cause or source of infection the more certain and more virulent would be the outbreak of
12387 typhoid. I can illustrate it by example. There would be as much danger to the city of Philadelphia through an infection of the water of the Schuylkill river by an outbreak of typhoid fever in Norristown, a city distant ten miles and having a population of about 16,000 or 17,000, as there would be from an outbreak of typhoid fever in Reading, a city distant about 70 miles and having a population of 80,000. The element of distance from the point of infection to some extent balances the size of the community, that is or might be the cause of the infection. A large city on a given water shed might be so far removed from the point of water works intake as to render practically remote the possibility of infection from typhoid developing in that city, and a small city may be so near the point of the water works intake as to render it very dangerous to the water supply of a given city if typhoid should develop in that smaller center. In other words, the distance of a center where the infection arises is certainly an element in determining the probability of a source of typhoid. And, in seeking the cause where this typhoid that is supposed to be due to polluted water supply the usual step taken is to begin at the water
12388 works intake and carefully exploit the causes up stream until one is reached, if it be reached at all.

Q. State in detail what position the science of bacteriology occupies in regard to the ascertainment of the purity of river water?

A. Bacteriology is a very important factor in determining the sewage pollution of a water supply, first in determining the number of bacteria per unit of volume of samples so collected for the purposes of analyses, but more especially in showing the presence, if they be present, of what are known as sewage bacteria, namely the bacillus coli communis, the several organisms of the proteus vulgaris variety or the stronger putrefactive and fermentative organisms that are usually associated only with decomposing organic material and are always accompanied or are always found in sewage polluted water.

Q. State in detail the place the science of chemistry holds in regard to the ascertainment of the purity of river water?

A. Chemistry is also another important factor in determining the degree of the pollution of a water supply in showing the condition of the nitrogeneous matter; to some extent the condition of the organic matter; the chlorine present
12389 which is a direct index of sewage contamination; and in showing changes taking place, especially in the nitrates and nitrites from time to time in the water.

Q. In the ascertainment of the quality of a river water what aid are chemistry and bacteriology to the sanitarian in forming a judgment of the quality and potability of a water?

A. It furnishes information on the quality of water that can not very well be had in any other way. It furnishes direct information along certain lines that can not be obtained in any other so called practical manner.

Q. In order to qualify as a sanitary expert is it necessary for such expert to have knowledge of chemistry and bacteriology?

A. I think it is. I think that a sanitary expert in passing on the value of a water supply should be able at least to interpret the bacteriological and chemical analyses and form an opinion as to the meaning of the different data that are given.

Q. Does not a sanitary expert call to his assistance all information available from chemical and bacterial sources
12390 as well as the knowledge of the sources of pollution in passing judgment on the sanitary character of a river?

MR. JEFFRIES: Objected to as leading.

A. When such information is to be obtained he does. There are times where hasty investigations are made of sources of water supply where a sanitarian may be compelled to rely entirely upon his knowledge of the water shed, of the population on that water shed, of the general slope of the water shed and of the probable rainfall, all of which factors may be readily gathered from the statistics of the United States Census Bureau or of the United States Geological or Coast Survey. Whereas analytical data showing the bacteriological and chemical conditions required to be of value should extend over a considerable period of time and take into consideration the usual seasonal changes that occur in the quality of the water supply that will take place in rivers or other proposed sources.

Q. As a sanitary expert availing yourself of all chemical and bacteriological knowledge which is available to you, what is your opinion as to whether a typhoid bacillus lying in the sediment of a polluted stream for a period of sixty days
12391 would be the cause of typhoid fever when taken into the human system, if it had remained in such sediment for that length of time?

A. I have no opinion whatever upon a proposition of that sort and do not like to offer an answer to the question. There is no data with which I am familiar indicating any such condition as is recited in the question, and I do not know that I could offer any better reason upon this than that given before with reference to the probable longevity of the typhoid organism in the sediment of a stream or in the water of a stream above the sediment, having stated in that answer that the chances were in my opinion that the longevity of the organism would be less if found in the sediment of a stream where the processes of organic decomposition were in progress.

Q. What is your opinion as a sanitary expert, based upon your examination of the tables introduced in evidence by Professors Long, Palmer, Burrill and Jordan, of the waters of the Illinois, Mississippi and Missouri rivers as represented by such tables which you have examined as to which of these three rivers from these analyses discloses the least amount of impurity or pollution?

MR. JEFFRIES: I object to the question as immaterial.

12392 A. Basing an opinion upon the technical data in the volume entitled Streams Examination previously referred to in my testimony I should regard the quality of the water of the Illinois River at Grafton as no worse and in some respects better than the mixed waters of the Illinois, Mississippi and Missouri Rivers at the point in the Mississippi River, below Grafton as shown by the data in the tables of technical data previously offered as a part of my testimony.

Q. How does the Missouri River at Ft. Bellefontaine or West Alton compare with the Mississippi River above Grafton and the Illinois River at Grafton?

Mr. Jeffries: I object to the question as immaterial.

A. From a bacteriological point of view the water of the Illinois River at Grafton is decidedly better than the water of the Missouri River at West Alton. Considering the suspended matter the water of the Illinois River at Grafton is superior to the water of the Missouri River at West Alton.

The same statement may be made with reference to total solids.

12393 The same statement may be made with reference to the nitrates and nitrites. The degree of nitrification being shown as greater for station 21 at Grafton, at the mouth of the Illinois River than for station 32, West Alton on the Missouri River.

Considering the chlorine alone the water of the Illinois River at Grafton would not be considered as good as that of the Missouri River at West Alton.

Q. If the Illinois River discloses a less amount of impurities than the Missouri what would be the effect of the water of the Illinois emptying into the Mississippi River at Grafton and subsequently uniting with the Missouri at its mouth upon the combined waters of the Mississippi and Missouri Rivers at the intake tower at the chain of rocks?

A. Considering the relatively small natural stream flow from the water shed of the Illinois River when compared with the stream flow of the Mississippi River above St. Louis and the stream flow of the Missouri River, and ignoring or setting aside the fact of the water of the Illinois River being either better or worse than that of the two larger streams the addition of the ordinary stream flow from the Illinois River to the combined stream flow of the other two rivers would not have much effect either way. In order to reduce this to a more

12394 definite statement I have prepared a table showing the relative areas of the drainage basins of the three rivers mentioned in the question, and assuming for the present that the mean rain fall would be the same over the combined drainage area of the Illinois, Mississippi and Missouri Rivers upon this basis, and omitting all flow of Chicago sewage or of water from Lake Michigan, of each 100 gallons of water flowing in the Mississippi River opposite the chain of rocks, 75 1-4 would come from the Missouri River water shed, 20 1-3 from the Mississippi River water shed and the remaining 4 4-10 from the Illinois water shed.

As a matter of fact, however, the mean rain fall over the whole area of the Missouri River watershed is not so great as that over the water shed of the Illinois and of the Mississippi Rivers and it is probable that of the total flow of water in the Mississippi River opposite St. Louis 70 per cent. can be charged or credited to the Missouri River water shed; 20 or 22 per cent. to the Mississippi water shed and the remaining 6 or 7 per cent. to the Illinois River water shed. In this case it is assumed that no water falls in the Illinois River except that due to the rainfall on its drainage basin.

12395 Q. Have you figured out the results, adding the flow from the drainage canal?

A. I have upon the assumption only that the mean annual rain fall is substantially uniform over the entire Mississippi River basin embraced in the water shed of the Illinois and Mississippi River above St. Louis and the Missouri River which is not as stated in the answer to the previous question, quite true, but for this purpose may be accepted as true. Allowing the least stream flow of the Illinois River at Grafton as reported by the U. S. Engineers in October, 1891, of 1,000 cubic feet per second and assuming the discharge from Lake Michigan through the drainage canal of 300,000 cubic feet per minute or 5,000 cubic feet per second and allowing for the discharge of sewage based upon 90 per cent of 85 per cent of the total water consumption of Chicago which produces a discharge of 424 cubic feet per second, the percentage of volume flow with the least recorded stream flow of the Illinois River at Grafton would be seven (7). Taking this flow into consideration and also taking into consideration the flow of sewage from Chicago plus the flow from Lake Michigan. Of the water flowing in the Mississippi River
12396 opposite St. Louis, 20 per cent would be credited to the

Mississipi river, 75 1-2 per cent. to the Missouri River and 2.96 per cent to the Illinois River, and 1.54 to the influence of the discharge of the Chicago sewage, or such water as is carried with the sewage into the drainage canal exclusive of the diluting water drawn from the Lake.

Q. Will you state upon what basis you base these calculations and the sources of your information?

A. The information with reference to the least stream flow of the Illinois River is obtained from a blue print furnished by Judge Springer at one time counsel for the Sanitary District of Chicago, in this case, and purporting to have been made up in the office of the trustees. The information with reference to the drainage area of the three rivers under considerations is supplied by the United States Census Bureau and checked against drainage areas furnished by the United States Coast Survey in water supply and irrigation papers. The information with reference to the discharge of 300,000 cubic feet per minute from Lake Michigan is obtained from the blue print supplied by Judge Springer as previously mentioned, and in like manner the per second sewage discharge is obtained from the same source with this difference that in the blue print the statement is made that 85 per cent. of the total sewage of Chicago is discharged into the drainage canal. I have seen fit to reduce this by ten per cent. because 85 per cent. is shown to be 85 per cent. of the total water consumption of the city in which is included the water used for street sprinkling and water used for other purposes, which will not probably find its way into the city sewers and will not be a part of the flow of the sewers. Therefore, in discussing the proportion of water consumed by the city which would be found in the sewers, I have been accustomed to limit it to 90 per cent. of such consumption for the reasons above given. 12397

This modification has been made in the volume of sewage discharged in order to allow for the per second discharge in the drainage canal.

That the data furnished from the United States Census Bureau for the purpose of my testimony consist of four sheets and shows the total drainage area of the water shed of the Missouri River, the total population distributed on that water shed and in addition to these also shows in answer to a request for such information the population of the principal cities 12398 and the distances from St. Louis of each of these cities.

This, then, is again divided for each branch of the main stream, as, for example of the Missouri River, the Big Sioux River, the Yellowstone, the Platte, the Kansas and the Osage River. The same data is supplied for the Mississippi River and its principal tributaries and among its tributaries is included the Illinois River, and for the purposes of comparison it also includes the total water shed and distribution of the population on the Deleware River above the city of Philadelphia, excepting the Schuylkill River and finally shows the drainage area of the Schuylkill River and the distribution of the population on its water shed.

I requested Mr. S. B. North, the Director of the Census to make this compilation from the statistics in his Bureau, indicating the line of investigation which I desired to pursue and the state of facts which were requested in order to enlighten me upon the problems embraced in this investigation.

Q. Will you produce and read the compilation concerning which you have just testified?

A. Yes sir, it is as follows:

12399 DRAINAGE BASIN OF THE MISSOURI RIVER.

Missouri River (including all tributaries)—

Area of water shed in square miles	520,088
(a) Population of water shed	5,120,607

Distance of principal cities from St. Louis and their population:

Cities.	Distance from St. Louis	Population.
Jefferson City, Missouri	110 miles	9,664
Kansas City, Missouri	261 "	163,752
Leavenworth, Kansas.	290 "	20,735
Atchison, Kansas	305 "	15,722
St. Joseph, Missouri	322 "	102,979
Omaha, Nebraska	440 "	102,555
Council Bluffs, Iowa	441 "	25,802
Sioux City, Iowa	530 "	33,111

Big Sioux River—

Area of water shed in square miles	10,000
Population of water shed	179,000
Distance of mouth from St. Louis	500

No large cities on this tributary.

12400

Yellowstone River—

Area of water shed in square miles	70,119
Population of water shed	49,002
Distance of mouth from St. Louis	1,165

No large cities on this tributary.

Platte River—

Area of water shed in square miles	89,742
Population of water shed	727,009
Distance of mouth from St. Louis	422

Distance of principal cities from St. Louis and their population:

Cities.	Distance from St. Louis.	Population.
Denver	980 miles.	133,859

Kansas River—

Area of water shed in square miles	60,496
Population of water shed	1,014,772
Distance of mouth from St. Louis	265

Distance of principal cities from St. Louis and their population:

Cities.	Distance from St. Louis.	Population.
Kansas City, Kansas	265 miles.	51,418
Topeka, Kansas	308 "	33,608

12401

Osage River—

Area of water shed in square miles	16,254
Population of water shed	531,765
Distance of mouth from St. Louis	107

No large cities on this tributary.

DRAINAGE BASIN OF THE MISSISSIPPI RIVER— ABOVE ST. LOUIS, MISSOURI.

Mississippi River (including all tributaries except Missouri river)—

Area of water shed in square miles	171.698
Population of water shed	8,409,076

Distance of principal cities from St. Louis and their population:

Cities.	Distance from St. Louis.	Population.
Quincy, Illinois	110 miles.	36,252
Burlington, Iowa	178 "	23,201
Rock Island, Illinois	241 "	19,493
Davenport, Iowa.	242 "	35,254
Clinton, Iowa	270 "	22,698
Dubuque, Iowa	325 "	36,297
LaCrosse, Wisconsin	423 "	28,895
St. Paul, Minnesota	545 "	163,065
Minneapolis, Minnesota	557 "	202,718

12402

Illinois River—

Area of water shed in square miles	32,081
Population of water shed	3,433,845
Distance of mouth from St. Louis	37

Distance of principal cities from St. Louis and their population:

Cities	Distance from St. Louis.	Population.
Peoria, Illinois	162 miles.	56,100
(c) Ottawa, Illinois	227 "	10,588
Chicago, Illinois	357 "	1,698,575

Rock River—

Area of water shed in square miles	10,231
Population of water shed	564,972
Distance of mouth from St. Louis	241

Distance of principal cities from St. Louis and their population:

Cities.	Distance from St. Louis.	Population.
(d) Rockford, Illinois	342 miles.	31,051
Beloit, Wisconsin	360 "	10,436
Janesville, Wisconsin	375 "	13,185

12403

Wisconsin River—

Area of water shed in square miles	12,823
Population of water shed	326,197
Distance of mouth from St. Louis	380

No large cities on this tributary.

Chippewa River—

Area of water shed in square miles	8,616
Population of water shed	107,096
Distance of mouth from St. Louis	490

Distance of principal cities from St. Louis and their population:

Cities.	Distance from St. Louis.	Population.
(e) Eau Claire, Wisconsin	530 miles.	17,517
Chippewa Falls, Wisconsin	542 "	8 094

St. Croix River—

Area of water shed in square miles	7,693
Population of water shed	128,023
Distance of mouth from St. Louis	510

No large cities on this tributary.

12404

Minnesota River—

Area of water shed in square miles	16,100
Population of water shed	396,770
Distance of mouth from St. Louis	545

Distance of principal cities from St. Louis and their population.

Cities.	Distance from St. Louis.	Population.
Mankato, Minnesota	615 miles.	10,599

Cedar River—

Area of water shed in square miles	12,037
Population of water shed	470,365
Distance of mouth from St. Louis	290

No large cities on this tributary.

Des Moines River—

Area of water shed in square miles	14,635
Population of water shed	513,516
Distance of mouth from St. Louis	140

Distance of principal cities from St. Louis and their population:

Cities.	Distance from St. Louis.	Population.
Des Moines, Iowa	283 miles	62,139

12405 DRAINAGE BASIN OF THE DELAWARE RIVER—ABOVE TRENTON, NEW JERSEY.

Delaware River (including all tributaries except Schuylkill River)—

Area of water shed in square miles	9,217
Population of water shed	1,430,367

Distance of principal cities from Trenton and their population:

Cities.	Distance from Trenton.	Population.
(f) Easton, Pennsylvania	42.5 miles.	25,238
Phillipsburg, New Jersey	42 "	10,052

DRAINAGE BASIN OF THE SCHUYLKILL RIVER—ABOVE PHILADELPHIA, PENNSYLVANIA.

Schuylkill River (including all tributaries)—

Area of water shed in square miles	2,008
Population of water shed	382,192

Distance of principal cities from Philadelphia and their population:

Cities.	Distance from Philadelphia.	Population.
Norristown, Borough, Pennsylvania	6 miles	22,265
Reading, Pennsylvania	43 miles	78,961
12406 Pottsville, Pennsylvania	89 "	15,710

Q. In making this request of the Census Bureau what
12407 was the basis upon which the population of the water
sheds of the respective rivers was computed from?

A. The drainage area was first established as accurately as possible on maps in the Census Office. After the lines had been laid down showing the extent of the river basins the Census Records for 1900 were then appealed to to determine the population falling within it. Then the counties were divided pro rata upon the proportion that fell either within or without the drainage basin. Of course the population of urban centers was easily obtained. The distance of those centers above St. Louis on the river, was obtained with dividers in the usual way.

Q. Does the mixing of the Illinois with the Mississippi and Missouri Rivers as mentioned in the foregoing answer, create any added danger to the already contaminated and polluted waters of the Missouri and the Mississippi Rivers at the St. Louis intake, in your opinion?

A. In my opinion it does not for two reasons. 1. The an-
alytical investigations reported on by Professors Palmer
12408 and others in Streams Examination and the other in re-
lation to the total flow of the Illinois River, including Chicago sewage and water drawn from Lake Michigan, the first indicating that the condition of the Illinois River at Grafton was no worse during the four specified months of 1900 than the same four months for 1899, prior to the opening of the drainage canal; and the second indicating that the total volume of flow of the

Mississippi River opposite St. Louis by far the smallest percentage comes from the Illinois Drainage basin even while considering the flow of the sewage of Chicago and the water from Lake Michigan as a part of the discharge from that river. Under these conditions it would be difficult to conceive of a pollution of the Mississippi River at a point below the confluence of the three rivers of junction of the three rivers, excepting the pollution of the Illinois River was very great with reference to the pollution of the two other streams which contributed to the body of water moving past the city of St. Louis.

Q. From all of your knowledge of conditions that obtain in and along the Illinois River what is your opinion as a sanitary expert as to whether the deleterious substances, infected
12409 matter, or pathogenic germs would come from the drainage canal, and the sewers of Chicago and reach as far down the Illinois River as the city of Grafton.

A. The information which I have with reference to the Illinois River and the quantity and quality of the stream flow, its physical characteristics and the technical data obtained from an examination of the water samples does not warrant the belief that infected matter from Chicago would be found in the Illinois River as far South as Grafton.

Q. Assuming that typhoid fever germs should be found in the Mississippi River at the chain of rocks, do you know of any way of determining from what sources such germs originated?

A. Taking into consideration all the facts and considering the three drainage basins, namely the Illinois, the Mississippi and Missouri upon each of which are found many cities, some of considerable population, like Peoria and Chicago on the Illinois drainage basin, and Dubuque, Davenport, Burlington, Des Moines, Rock Island, Moline and Quincy on the Mississippi River basin—Kansas City, Topeka, St. Joe and Omaha on the Missouri basin, in all of which cities it is probable that typhoid fever prevails during the usual season of typhoid fever and in some of these cities prevails at all times, and especially keeping in
12410 mind the larger cities close to St. Louis, it would be wholly impossible in my opinion to say from what city the typhoid fever organism found in the Mississippi River op-

posite St. Louis would come. If it were true that any one of the cities on either of the water sheds not too far removed from St. Louis had typhoid fever while the other cities on the other watersheds did not have it, after allowing for the usual time between the infection of the stream and the discovery of the organism at St. Louis it might be charged to that city, whichever one it might be, but statistics show that in all the larger cities of the country typhoid fever always prevails, and where the drainage of three water sheds combined as in the Mississippi River in front of St. Louis I know of no process whereby the typhoid fever organism there found could be assigned to the probable locality from which it came.

Q. What is your opinion, as a sanitary expert, as to whether the germ of typhoid fever could lie in the sediment of the drainage canal or upon the bottom of the Illinois River for a period of from one to three years?

A. I have no data that would bear out such an assumption. And I do not know of any experiments ever made that 12411 would furnish reasonably exact information upon the matter similar to that embraced in the question.

Q. What is your opinion as to whether a typhoid bacillus deposited on the bottom of the Illinois River could remain there for a period of upwards of five years and then be stirred up by the action of the waves, wind, steamboats, or by any other means and continue its journey down to St. Louis and be a cause of danger to the inhabitants of the State of Missouri and the citizens of St. Louis using the water of the Mississippi River for drinking and domestic purposes?

A. In my opinion such conditions could not exist. I do not think that a typhoid organism would live for five years in the sediment of a river. A fact calculated to fortify this view can be offered in connection with the investigation of what is known as the Dayton Sand Bar in the Ohio River north of Cincinnati, which for many years was regarded by many intelligent people in Cincinnati as the proper source of water supply for the city. At the time the investigations were going forward looking to the development of plans for the improvement of the water supply of Cincinnati, wells were sunk for a depth of 70 feet, in

this sand bar, and samples of water drawn from the bot-
12412 tom of such wells. The organisms found in samples of such
water indicated that organic matter deposited ages before the investigation mentioned was still undergoing decomposition for all of the bacteria found upon the plates cultivated from the samples of water were of the putrefactive variety, but there was nothing to indicate the presence of pathogenic bacteria in the water found at the bottom of these test wells. The results of this examination will be found briefly reported in the report of the engineering commission for the extension and betterment of the water works of Cincinnati, previously mentioned in this testimony.

Q. Was the Missouri River, in your opinion, a safe water for drinking and domestic purposes prior to the opening of the drainage canal in 1900?

Mr. Jeffries: I object to the question as immaterial.

A. Basing my opinion upon my knowledge of the investigations conducted by the city of St. Louis in the filtration of the water supply of that city and reported from time to time in the reports of the water commissioner for the past ten years; upon the data collected by the Commission of Hydraulic Engineers
appointed to report a plan for a new water works or for
12413 the improvement of the present water supply of the city
of St. Louis in 1902, and from my knowledge gained by personal investigation of the waters from rivers not materially unlike that of the Mississippi River at St. Louis I do not believe that the water was fit for drinking and other domestic uses prior to the opening of the drainage canal nor for many years prior to that event.

Q. Was the Illinois River water a safe water for drinking and domestic purposes prior to the opening of the drainage canal in January, 1900?

A. I would give the same answer to that question also.

Q. Was the Mississippi River above Grafton a safe water for drinking and domestic purposes prior to the opening of the drainage canal?

A. I would give the same answer to this question, excepting, of course, with reference to the investigation of the water supply for the city of St. Louis.

Q. Do you regard any river that receives the sewage of 12414 rural and urban population as a safe drinking water without mechanical treatment of some kind?

A. I do not.

Q. Has the sanitary condition of the water of the Illinois River at Grafton been improved or damaged by the opening of the drainage canal?

A. Basing an opinion upon the technical data before me applicable to this question, upon the whole the condition of the water appears to be improved.

Q. Since the opening of the drainage canal are the waters of the Illinois River less sanitary than the waters of the Missouri and the Mississippi River?

A. No.

Q. What effect, in your opinion, does the water discharged through the drainage canal have upon the waters of the Mississippi and Missouri Rivers at the chain of rocks?

A. Assuming that the opinion which I have given as to the quality of the Illinois River at Grafton is no worse after the opening of the drainage canal than it was (as shown by the technical investigations) before the opening of the drain- 12415 age canal it would have no marked influence on the quality of the combined water of the Mississippi River passing the chain of rocks.

Q. Taking into consideration all knowledge that you possess in regard to the chemical, bacterial and physical conditions of the water of the Illinois River and its tributaries by the towns sewering into the Illinois River and its tributaries above, upon the water shed of the Illinois River, both rural and urban, the stages of the river under all conditions and during all seasons, together with the conditions that obtain or seem to occur upon the Missouri and Mississipi Rivers, what is your opinion as to the effect of flowing sewage from Chicago to the drainage canal into the Desplaines and Illinois River, upon the inhabitants of the State of Missouri using the water of the Mississippi River for drinking and domestic purposes?

A. Assuming that the bacteriological and chemical investigation applied to a water supply are acceptable as showing

whether it is or is not fit for domestic uses, and assuming
12416 further for the purpose of answering these questions that
no objection existed as to the quality of the water supply prior to the opening of the drainage canal, but that it was regarded as a suitable drinking water and for other domestic uses, I can see no reason to doubt its present suitability, notwithstanding the flow of sewage through the drainage canal plus the flow of water from Lake Michigan. In this answer I do not wish to be understood as indicating that the water from the Mississippi River at the chain of rocks has been for many years, if it was ever suitable for drinking and other potable uses, and I wish to be understood simply as stating that there is no evidence before me showing such change having occurred in the quality of the water as to render it less desirable for potable purposes or more deleterious to health than existed prior to the opening of the drainage canal.

Q. From a study of all the typhoid statistics as they obtain along the water shed of the Missouri River, the Mississippi River, the Illinois River, the city of Chicago and the city of St. Louis, and assuming that the increase of typhoid fever cases as
evidenced by the death rate in St. Louis, and disclosed by
12417 the Board of Health reports of the city of St. Louis,
under typhoid fever deaths there reported and taking into consideration all chemical, bacterial and other knowledge which you possess, what is your opinion as to whether such increase in typhoid fever, assuming there was an increase as above indicated in St. Louis, since the opening of the drainage canal, can be attributed to the opening of the drainage canal, as the direct, immediate and approximate cause of such increase beyond all reasonable doubt?

A. If the typhoid fever statistics of St. Louis show an increase in the rates per unit of population since the opening of the drainage canal and the investigation clearly indicates that there is no other possible source of infection and the rates in St. Louis rise correspondingly with the rates in Chicago and fall correspondingly with the rates in Chicago, it might be held that such increase in the unit rates for typhoid fever in St. Louis could be charged to the flow of sewage through the drainage canal, but in view of the possibility of infection from other

urban centers than Chicago, and especially in view of the possible infection of the St. Louis water supply from typhoid fever prevailing in Peoria, I should hesitate to charge to the flow
12418 of Chicago sewage through the drainage canal any increased typhoid rates shown in the city of St. Louis since the opening of the canal unless the evidence clearly disclosed the fact that as the rates raised in Chicago they raised in St. Louis and as they declined in Chicago they also declined in St. Louis. In other words, unless the rates in St. Louis showed that they corresponded with the rates of the city supposed to be the cause I am lead to this opinion by the much nearer source of infection in the city of Peoria, where typhoid fever prevails during the usual season of typhoid and doubtless is found prevailing to some extent throughout all the months of the year. Or, in other cities of large population upon the water shed of the Mississippi and Missouri Rivers. While one can not positively say that the sewerage of Chicago might not contribute to this or certainly does not contribute to this, it is equally out of the question to assert that a single city discharging its sewerage into one of the rivers constituting the drainage area of the river which went in front of the St. Louis intake is the sole cause or at all the cause of the increase of rates in the city of St. Louis. Too many factors enter into the proposition such as is contained in the question to justify one in asserting that typhoid fever is due
12419 to any one of several possible centers of infection lying on the drainage basin above the city of St. Louis.

Q. Assume that the city of St. Charles located within 47 miles of the intake tower of the St. Louis water works containing a population of 7,000 with more typhoid fever present than in the city of Peoria, which city of Peoria is located 286 miles above the city of St. Louis, what would be the comparative effect of these two cities upon the water supply under the conditions assumed?

A. The smaller city, namely, St. Charles, being nearer the point of intake above the city of St. Louis in my opinion would constitute a greater menace to the water supply of that city than would the larger city of Peoria, situated five times as far away in point of distance from the intake of St. Louis even though the normal rate of typhoid fever were the same in the two cities.

I have always believed and can point to no evidence that contradicts this belief, that the nearness of the point of infection rather than the size of the urban or rural center is the chief factor in determining infection. That the little city near by in which typhoid fever prevails is more to be feared than a large city far distant even though the same unit rate of typhoid is found in each.

12420 Q. I call your attention to two charts introduced in evidence and sworn to by Professor W. P. Mason under the caption "Deaths from typhoid fever, as reported in Chicago and St. Louis Official Health Reports, the deaths in St. Louis platted one month in advance, i. e., February deaths are platted as of January," and ask you to look at these charts assuming them to be based upon correct statistics and properly platted and ask you to state whether the typhoid deaths in St. Louis bear any relationship to the typhoid conditions that obtain in the city of Chicago?

Mr. Jeffries: I object to the question for the reason that in the compilation of the charts shown to this witness Professor Mason did not take into account variations in the temperature of the water, the velocity of the water, the volume of the water and other natural conditions which would exert a material influence upon the sanitary condition of the water in the Illinois River and for that reason the charts so referred to do not properly display the actual conditions existing at all times through the year and which must be taken into consideration in determining the effect of the sewage of Chicago upon the mortality of the city of St. Louis, and the effect of such variation in the sanitary
12421 condition of the water produced by the variations heretofore referred to, is as important to be considered as the determination that such increase in the typhoid death rate in the city of St. Louis has increased because of the opening of the drainage canal.

A. An examination of the diagrams for the year 1900 to 1903, inclusive, in which the solid lines show the charted deaths by months for the city of Chicago and dotted line the same data for city of St. Louis for each of the years embraced, and which in the legend at the top of each of the pair of diagrams a statement is made, and considering the statement in the legend at the head of the two pages before me, showing that the deaths in St. Louis are platted one month in advance, namely that February deaths are platted as of January, presumably for the purpose of comparison of the deaths in St. Louis directly with the deaths from typhoid fever in Chicago, it does not appear that the typhoid fever death rates from St. Louis are coincident in intensity with the typhoid fever death rates of Chicago. This is especially true for the years 1901 and 1902 and 1903. For which years the diagrams show that when the rate is rising in Chicago it is declining in St. Louis and when it is declining in Chicago it is sometimes rising in St. Louis, and that the wide 12422 ranges in the typhoid fever death rate as shown in the diagram for the city of Chicago are not reproduced in the diagram showing typhoid fever death rates for the city of St. Louis, and it would not be possible in my opinion to connect the rates in one city with the other. In fact there might be just as close an agreement between the typhoid fever rates of the city of Chicago and Philadelphia if plotted together in this manner as there is between the typhoid fever death rates of the cities of Chicago and St. Louis, and clearly the typhoid fever rates of Chicago can have in this manner no influence whatever upon the typhoid fever rates of Philadelphia. There is nothing on the face of the four diagrams to indicate a connection between the typhoid fever death rates of the two cities.

Q. Assume that in the city of St. Louis there existed in 1895 4,800 wells and assume that the city chemist after an examination of about 50 of these wells condemned them as being unsanitary and polluted and assume further that the board of health of the city of St. Louis ordered the city chemist to desist from the examination and condemning of wells and that such wells still exist in the city of St. Louis, what, in your opinion would be the effect upon the typhoid conditions in St. 12423 Louis as attributed to wells in that number in a city the size of St. Louis?

A. As a general proposition wells in built up communities like the city of St. Louis, unless they are deep artesian wells or wells driven to a great depth in rock are always open to suspicion as possible sources of illness and disease. This is due to the fact, as previously stated in this examination, that the soil will in due time become polluted from organic waste, from leaky sewers and connections to sewers, from leeching cess pools and privy vaults where these exist and it is possible that where a well is open to infection from the faeces of a typhoid fever patient it may become the center of infection and cause of wide spread disease. This fact is so well recognized in the large cities that there are few cases where wells are still used as sources or drinking water, provided the city is able to supply mains to carry the water to such localities, and the condemnation of open shallow wells or wells sunk in the drift by the local health boards is a matter of frequent occurrence in the larger cities where such wells are known to be still open to use.

12424 Personally I should regard every such well in the city of St. Louis the water of which is liable to be used for drinking as a menace to the public health excepting the well is so far removed from possible sources of pollution as to be reasonably safe from the contents of vaults and cess pools leeching through the surrounding soil.

ADJOURNED until 9:30 A. M. the next day, March 29, 1904.

Tuesday, March 29, 1904, 10:00 A. M., City Hall.

12425 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

J. W. HILL

resumed the stand for further direct examination by Mr. Todd, and testified as follows:

Q. If in your opinion the water supply at the chain of rocks which consists of the combined waters of the Illinois, Mississippi and Missouri Rivers is an unsafe and unfit water for drinking and domestic purposes in its raw state, or as treated at the present time by the settling basins of St. Louis, what is your opinion as to how said water should be treated in order to get a safe and wholesome water for drinking and domestic purposes?

Mr. Jeffries: I object to the question as immaterial.

A. By filtration.

Mr. Todd: Q. In passing upon the question of filtering the water at St. Louis, assuming that as an engineer having
12426 this problem under consideration, what consideration would you give to the sewage entering the drainage canal from Chicago in passing upon the question of filtration at St. Louis?

Mr. Jeffries: I object to the question as immaterial.

A. No special consideration would be given the sewage of Chicago running into the head waters of the Illinois River which forms one of the tributaries of the Mississippi River.

Mr. Todd: Q. Have you made any investigations touching upon the population living upon the three water sheds above St. Louis, of the Illinois, Mississippi and Missouri Rivers?

A. I have.

Q. What investigations have you made, Mr. Hill, and what was the purpose of this investigation?

A. The purpose of the investigation following the usual custom in determining the probable degree of pollution of water flowing in a stream that is drawn upon or is about to be utilized as a source of public water supply was to show first, the
12427 distribution of population on the three water sheds per square mile, next to locate the center of gravity, next to relate the urban population on each water shed to St. Louis as a point of water intake. The first step in the investigation was to divide the total population on the water shed by its area from which is derived the distribution of population per square mile of drainage basin.

Next the population of each urban center was divided by the distance of the center from the St. Louis intake. The quotients thus obtained were averaged and the total population divided by the sum of the quotients, fixing thus the center of gravity of the population on each water shed. The effect of this operation was to give a numerical value showing the relative probable degree of pollution of the water flowing past St. Louis from each of the respective drainage basins. The next step was to take the mean of all quotients obtained by dividing the population of the urban centers by the distance of each center from St. Louis, and this gave a factor that fixed the probable center of pollution on each drainage basin.

Further investigations were made along this line comparing St. Louis with Philadelphia and with Hamburg in Germany.

12428 Comparisons were subsequently made with reference to the city of Philadelphia by drawing its water partly from the Delaware and partly from the Schuylkill rivers to determine the relative degrees of pollution in those two streams.

A further step along this line was made in the following manner: The total drainage area of each of the three water sheds was stated and added together. The water shed then of each of the drainage basins was divided by the total water shed of the three drainage basins, to obtain a factor which would show what proportion of the water flowing in the Mississippi River below the confluence of the Illinois and Missouri Rivers with the Mississippi came from each of the respective drainage basins. Upon the assumption that there was a uniform amount of rainfall over the entire area stated in evidence yesterday, which is not strictly true. The amount of rainfall on the Missouri water shed as an entirety would be less than on the Mississippi River water shed above St. Louis and on the Illi-

12429 nois water shed and would modify the figures that were thus obtained.

Mr. Jeffries: That is it would be proportionately less?

A. It would be a good deal less and it would reduce this proportion, that is to say instead of seventy-five per cent. of the water flowing past St. Louis coming from the Missouri water shed it would be more nearly correct to state it as from 70 to 72 per cent., and this would correspondingly raise the discharge of the Illinois and the Mississippi Rivers.

Following the several methods above mentioned to arrive at the probable pollution on each of the several water sheds contributing water to the Mississippi River at St. Louis, the following results are obtained:

The distributed population per square mile of water shed of the Missouri River is 9.94.

The distributed population per square mile of the water shed of the Mississippi River above St. Louis is 43.21.

The distributed population per square mile of the water shed on the Illinois River is 107.00.

The urban population collected in the cities on the Mis-
12430 souri water shed is 2.00 per square mile.

The urban population collected in the cities on the Mississippi water shed is 9.00 per square mile.

And the urban population collected in the cities on the Illinois water shed is 72. per square mile.

Referring especially to that part of this answer in which the statement is made that the respective population of the urban centers on each of the urban centers of 4,000 or more people are divided by the distance of such centers from the intake of the St. Louis water works and in which the total population has been divided by the mean of the quotients thus obtained, a factor is obtained for each stream, as follows:

For the Illinois water shed	209.2
For the Mississippi water shed	122.47
For the Missouri water shed	106.56

The relation of these numbers to each other indicates inversely the relative value of each stream as a source of water supply with respect to sewage pollution from all sources.

That is to say the Missouri water shed would have the
12431 highest value; the Mississippi water shed next and the
Illinois water shed the lowest value as a source of water supply for the city of St. Louis.

Mr. Todd: Q. In figuring out the value you take into consideration in answering the question, and in the answer just given, the volume of the three rivers and the relations in which they each stand to the other as they pass St. Louis?

A. In the calculations just mentioned no consideration is given to the flow of water in the stream whatever. This statement is entirely independent of the flow in each river. That is with reference to the figures which were obtained to show the relative value of the different water sheds as sources of supply. because it deals alone with the population gathered in urban centers and the distance of said centers from St. Louis.

Q. What effect would the volume of flow have upon the question involved in the last answer given by you?

A. It would have this effect, if the flow of each of the several streams was as an average the same, it would not change the relation established showing the relative value of the 12432 water sheds as sources of public water supply.

If, however, the flow was greatest from the Missouri River drainage area which normally would be the most available source of supply and least upon that water shed which by the previous showing is the least desirable, namely the Illinois River, it would mitigate the objections to the greater degree of normal pollution by reason of larger population and shorter distances from St. Louis on the Illinois River drainage basin. For example, if the flow of the Illinois River was one per cent. of the total flow of the Mississippi River in front of St. Louis, then notwithstanding the fact that this is the most objectionable drainage basin to draw from its influence when compared with the other 99 per cent. of water derived from the Missouri River and the Mississippi River it would probably not be appreciable.

Q. Applying the information just introduced from the evidence by you from the three water sheds to the question of filtration of the water supply at St. Louis, what bearing would that information have upon that subject?

Mr. Jeffries: I object to the question as immaterial.

12433 A. It would have none at all because any investigations preceding the development of a scheme of filtration of water for the city of St. Louis or of any other city would be mainly devoted to the collection of data with reference to the water flowing past the proposed point of intake and no serious considerations would be given to the sources from which the pollution found in such water came.

Mr. Todd: Q. From your investigation of the water supply at St. Louis which takes its water from the co-mingling of the Illinois, Mississippi and Missouri rivers at the intake tower at the chain of rocks what conclusion do you draw as to how that water supply compares with the other water supplies of the cities of this country and in Europe with which you are acquainted?

Mr. Jeffries: I object to the question as immaterial.

A. I have made a comparison of the conditions of the three cities, namely, St. Louis, and Philadelphia with reference to the Schuylkill River alone, and Hamburg, Germany, drawing its water supply from the Elbe River?

A. Assuming that the city of St. Louis drew its water sup-

ply wholly from the Illinois River drainage basin. I have considered the total drainage area of each of the three
12434 drainage basins. That is I have considered the urban and total population on each of the drainage basins and I have finally developed the factor in the manner explained in the answer to the previous question, which in my opinion shows the relative advantage or disadvantage of the source of water supply of the three rivers mentioned with respect to the three cities drawing their water supply wholly or partly from the sources under consideration. The size of the numbers thus obtained indicates the objection to each source of water supply as follows: For the city of St. Louis on the assumption that the water supply is drawn only from the Illinois River basin there is 209.20; of the city of Philadelphia upon the assumption that the source of water supply is drawn from the Schuylkill River 330.63; and for Hamburg which draws its entire water supply from the Elbe River 698.12. The lower figure by this method of comparison would indicate the best source of water supply, and if my method of reasoning is correct it would show that under the present conditions the Illinois River would be a safer source of water supply for the city of St. Louis than is the Schuylkill River for Philadelphia or the Elbe River for Hamburg. The water
12435 of the Elbe River at Hamburg is now and has been for 11 years past all filtered. Preparations are going forward to filter the water supply at Philadelphia from the Schuylkill as well as from the Deleware River.

And by the same process of reasoning it seems to me that the water supply of St. Louis should be filtered in order to remove any natural objections that exist to the sources from which its water is taken.

Q. Would it cost any more to filter the water of the Mississippi River at the chain of rocks with the water of Chicago entering the drainage canal as it now does than it would if the said sewage of Chicago was eliminated?

A. It would make no difference whatever, either in the cost of construction or the cost of operation of a system of filters for the city of St. Louis. From a reasonable experience in constructing and operating works of filtration on a large scale it is clearly shown that the sewage pollution of a river is not the feature that

increases the cost of filtering a polluted water. That material which rapidly clogs the filters requires their cleansing from time to time is mud and silt flowing in the river and repre-
12436 sented in the analysis as suspended matter, of which the bacteria from sewage sources constitute by weight or volume an infinitesimal part. It is not known that what we term mud, excluding bacteria, is in itself a particularly objectionable element in water, at least it is not known that it is the cause of disease or disorders in the human system and is chiefly if not wholly objectionable from an aesthetic point of view.

I feel that the experience at Philadelphia with the filters that have been operating at the Roxborough stations, some of them for 21 months and others for a period of nine months, in daily service, dealing with upwards of 23,000,000 gallons of water per day, showing clearly that the varying degrees of pollution in the Schuylkill River as determined by the bacteriological and chemical analyses have no influence whatever either upon the efficiency of the filters, of their cost of operation, but when the Schuylkill River is in flood and large quantities of clay and soil are being brought down from its drainage basin to Philadelphia, this material does have an influence in effecting the cost of operating the filters, and to a limited extent has some influence on the efficiency, at least with reference to the
12437 turbidity of the water filtered.

Q. Applying the experience which you have had with the Schuylkill to the waters of the Mississippi River as the same pass the intake and the knowledge which you have of the three rivers, the Illinois, the Mississippi and the Missouri, which one of the three rivers thus mentioned would create the largest percentage of cost in operating a filtration plant at St. Louis?

Mr. Jeffries: I object to the question as immaterial.

A. The Missouri river, by reason of the very large amount of suspended matter brought from its water shed and contributed to the suspended matter of the mixed waters of the two other rivers opposite St. Louis; and the difficulty of filtration of the St. Louis water will be found to be wholly due to the silt and other suspended matter in the Mississippi water at St. Louis, obtained very largely from the Missouri River drainage basin. The sewage condition at St. Louis, I should regard as involv-

ing no special difficulty whatever and I base this opinion upon careful study of the report of the last commission of en-
12438 gineers appointed to investigate the water supply of that city.

Q. That was the Merrimack commission?

A. Yes sir.

Q. Who made that report?

A. That report was made by a commission consisting of Benezette Williams of Chicago, Mr. George Y. Wisner of Detroit, and Allen Hazen of New York.

Q. That is the report where Mr. Hazen filed a minority report, defending the filtration of the Mississippi River?

A. Yes sir, that is right. The majority of the commission recommended the Merrimack scheme.

Q. Would the Mississippi and Illinois, exclusive of the Missouri River cost as much to filter as the Missouri?

A. No, they would not for the reason, that the percentage of suspended matter is lower in each of the two rivers, namely the Illinois and Mississippi river than it is in the Missouri River.

Q. Question repeated.

A. No. It would not cost as much because of the lower
12439 percentages of suspended matter in the two rivers mentioned.

Q. Would the amount of infection in the river, meaning by that sewage infection, create an added cost to the operation of the filters?

A. No, it would not. If the water through a system of filters was free from sand and silt and soil that can be charged to the wash of the banks of the river or of the water shed of the river what we would term city sewage could be filtered provided it was mixed with the same volume of water as that flowing in the stream into which it is discharged. In cleaning filter beds such as are in use in the city of Philadelphia and elsewhere it is found that practically all the material moved from time to time would be classed as mud, and if it were possible to so separate this mud at the surface of a sand bed into organic and inorganic material, and include the bacteria as a part of the

organic material, the organic matter would bear such a small relation to the total amount of material collected that the cost of filtration prorated on this would be an insignificant
12440 amount, and after all the real cost of operating filters is represented by the efforts to remove from a polluted water the suspended matter exclusive of the bacteria, and that matter which usually imparts turbidity to the water.

Q. If a water should be highly infected with typhoid germs would the fact that the water was highly infected create any added cost in the construction or operation of a filter?

A. None whatever.

Q. Assume that a filter plant should be established at the city of St. Louis sufficient in size and suitable for the demands required, would the fact that the Mississippi River at the chain of rocks vary from time to time from slight infection to large infection, create any added cost in the operation of such filter?

A. None whatever.

Q. Would it require any more skilled and expensive operators to handle a filter that would meet the demands of the city of St. Louis under low infection than it would under a high infection existing in the waters of the Mississippi River under present conditions?

A. The dgree of sewage pollution or of infection of water
12441 coming to the filters would not be a factor either in determining their cost of construction or cost of operation. Evidence along this line is best shown, in my opinion, by the regular tests which I am having made of the raw waters applied at our Roxborough filter station, and of the filtered water afterwards to determine the presence of the colon bacillus, deeming this a more delicate test of the operation of sand filters than the comparison of numbers of bacteria in the water before and after filtration. These tests which are regularly made two or three times each week reveal the fact that upon exceedingly rare occasions is the colon bacillus found in the filtrate of any filter while we seldom fail to find it in the applied water. Reducing the operation of the filters with respect to the colon bacillus to percentages, it shows that under the worst conditions of the operation of our filters we have removed from 96 to 99 per cent.

of the colon bacillus and in making this determination I am excluding from consideration altogether a great majority of the times when it is not found at all in the filtrates.

Q. In passing judgment upon the value of a water supply as based upon the population does that judgment take into consideration the condition of the river as determined by
1242 the chemical and bacterial condition of the water and the volume of flow?

A. No, it does not and is based solely upon the factors noted, namely the area of water shed population on the water shed considered as an entirety, population gathered in the urban cities of 4,000 or more people and finally the distances of each of these centers from the water the intake.

Q. How does that method which you have just indicated compare with the chemical and bacterial examination covering a long period of time of the waters of the river and the volume and size of the river?

A. Excluding the soil, grains of sand and silt which are found in varying quantities in different rivers, and excluding the difference in the volume of flow of such rivers, it must be held and is held at times that the chemical condition or bacterial condition of the several rivers so compared would be sub-
1243 tanially the same. That is to say that the sewage pollution of the stream would depend upon the number of people contributing to it, other things equal. 2,000 people would be a greater objection upon a given water shed than 1,000 people and the probable sewage going into the stream would be twice as great from 2,000 people as from 1,000 people. By this process of reasoning it would be fair to assume the sewage pollution of any stream bears a just relation to the population gathered upon its water shed when modified by the distance of center of population from a proposed point of water intake.

Q. Question repeated.

A. The chemical and bacteriological investigations show in reference to the city of St. Louis that the Illinois River is the better source of supply, while the physical investigation that has been described show that it is the least desirable source of supply. If we had no chemical and bacteriological data and

were approaching the problem as a new proposition we
12444 would fix the center of population of the Illinois River water shed nearer the St. Louis intake than that of the Mississippi and Missouri water sheds. This mode of comparison of water sheds wholly ignores the volume of flow in each stream.

Q. Where the information is obtainable showing the chemical and bacterial conditions of the river, and its volume of flow and the information is also obtainable showing the population upon the water shed in the methods here described of a given river, which method furnishes the most accurate way of arriving at a correct judgment of the quality of such a river?

A. The technical analyses of the water itself at any definite point?

Q. In considering the question of filtration as applied to St. Louis, would the percentage of water passing over
12445 the Bear Trap Dam at Lockport, which represents the mixed sewage of Chicago and the water of Lake Michigan, as the same arrives at the chain of rocks at St. Louis comingling with the waters of the Illinois, the Mississippi and the Missouri Rivers be a factor of expense either in maintenance or operation or installation of a filter established for the filtration of a municipal water supply of the city of St. Louis?

Mr. Jeffries: I object to the question on the ground that it is immaterial.

A. It would not.

12446 CROSS-EXAMINATION, by Mr. Jeffries.

Q. What are the elements of cost so far as the condition of the water is concerned in the construction and operation of a filtration plant?

A. The element of cost in the construction will be the area of filters required to deal properly with the given water. The element of cost in operation would be represented by the period of operation of the filters between successive cleanings and the amount of material to be scraped and cleaned from the filters at the end of each such period, that is to say, with a water carrying large amounts of suspended matter, the rate of filtration per unit of surface would be less than with a water carrying smaller amounts of suspended matter.

Q. Why is it necessary to clean the filters?

A. Because of their becoming clogged at the end of what is termed the period of operation.

Q. What would be the result if they were not preperly cleaned?

A. The filter would fail to deliver the required amount of water by reason of the clogging of the sand bed at the surface.

Q. Would this clogging in any way produce a perversion of the sand bed?

12447 A. No, it would not; it would simply create a mass of matter in the interstices of the sand bed at and near the surface such as to prevent the usual rate of flow per unit of sand area.

Q. Is this unit of sand area graduated by the amount of infection that is supposed to exist in the water?

A. No, it is not. It would be graduated entirely by the total amount of suspended matter found in the water as an average through the year of operation.

Q. The more suspended matter—

A. The larger the area to filter a given amount of water, because of the smaller rate of percolation per square foot of sand.

Q. As to the depth of the sand bed what bearing has the infection upon the necessary depth?

A. None whatever. In fixing the thickness of sand beds I do not know that the possibility of infectious matter in the water has been a factor, if taken into consideration at all. As a matter of fact the sand beds are of varying thickness in filters built by different cities. They are likewise of a varying size of sand grains within reasonable limits. The custom is when a new filter has been constructed to furnish it with the maximum thickness; a sand bed which for this purpose may be put at
12448 40 inches in depth. Such sand bed is scraped from time to time as the filter is taken out of service until the least thickness is seldom less than twenty inches, such a filter is once more scraped and the entire bed of sand is restored to the original thickness of say forty inches.

It is believed, and I think proven by my personal experience, that filtration is as well accomplished with a twenty inch sand bed as with a forty inch sand bed, but it is doubtful to my mind as to whether thicknesses of less than twenty inches could be used in order to insure at all times a satisfactory quality of filtered effluents.

Q. Is it not a fact that water sometimes becomes very greatly infected and requires double filtration?

A. There are examples, notably at Bremen in Germany, where the water is run first through one filter and then through another filter of the same size, in which the rate of percolation is maintained the same as in the former filter. This is with a view to improving the quality of the filtrate. The same method or custom prevails in the waterworks at Schiedan, Holland. In our waterworcks at the Lower Roxborough station all the water is twice filtered, once at the high rate through roughing 12449 filters and a second time at a low rate through the plain sand filters. In the Philadelphia experience, however, this is done in order to admit of a reasonable and a normal rate of percolation in the second set of filters and not primarily with a view to guarding against unsatisfactory filtration of the water in the second set of filters. It may be said with reference to the Philadelphia experiments that the water from the primary or preliminary filters is not regarded as satisfactory for use at any time.

Q. In the construction of a filter plant do you take into consideration the character of the watershed, the volume of water in the stream, together with the chemical and bacterial determinations of that water?

A. In fixing the preparations and method of operation in filters, no consideration is given to the area of the watershed or to the population gathered upon it. And this condition would form a factor only for the purpose of comparing conditions as between two proposed sources of supply. The final factors that would enter into consideration of the size and method of operation of filters would be determined by the chemical and bacteriological analyses of samples of water taken from the 12450 selected stream or other source of supply at the proposed point or existing point of intake.

Q. In the operation of filtration plants is it customary to entirely eliminate all bacteria from the water?

A. Eliminate all from the filters?

Q. Yes.

A. Upon rare ocassions it has been shown that the entire number of bacteria have been eliminated from the filter effluents. That experience has been had with our own filters here in Philadelphia and has also been had with the filters in London. As a general proposition, however, there is remaining in the water after filtration very rarely more than one or one and a half per cent. of the original number of bacteria found in the applied water.

Q. And that percentage varies according to the efficiency of the plant and its operation?

A. It does.

Q. The more infected a water becomes the more important it is for a thorough and efficent construction and operation of a filtration plant, is it not?

A. The degree of infection in the water would not affect
12451 the cost of construction but it would affect the grade of
sand used in charging the filters with filtering material. If the source of supply is known or believed to be materially infected it should call for greater care and vigilance in the operation of the filters. That is to say if filtration has for its object the removal or material reduction of sewage pollution in the applied water it would require denser beds of sand and more care in the operation than if the sole purpose was to remove suspended matter not of a deleterious character, or for the purpose of removing simply mud from the water, but this does not necessarily involve either increased cost of construction or increased cost in operation.

Q. It may do so, however?

A. It is not likely, Mr. Jeffries. The result would be to reduce the size of sand in the bed, that is to say it would be a denser bed, not quite so coarse, and it would demand closer attention on the part of the filter manager who should keep in close touch with the daily operation of the filters.

Q. And as you reduce the size of the grains of sand, or as you

employ denser beds of sand, the slower the process of
12452 filtration becomes does it not?

A. That would be true provided there is no preliminary filtration of the water such as we have made a part of the system of filtration for Philadelphia.

Q. Is it not true that water would percolate through rough grains of sand more rapidly than through dense grains of sand?

A. It will.

Q. A given quantity of water will pass through a bed of sand consisting of coarse grains more rapidly than through a bed of sand composed of fine grains?

A. It will. The rate of percolation will be most rapid in the more porous bed of sand.

Q. And as the degree of diminution in the character or size of the sand grains, the slower the process of filtration upon a given area?

A. That is true.

Q. The population of the area drained by the Illinois River including the city of Chicago is greater per square mile than that of either the Missouri or Mississippi, is it not?

12453 A. It is.

Q. Now then taking into consideration the center of population, I understand you to say that the waters of the three rivers, and that was the Illinois, the Missouri and the Mississippi, are represented by the figures 209.2 for the Illinois; 122.47 for the Mississippi, and 106.56 for the Missouri. That, I understand, is the relative value that the waters bear towards each other at a given point in the stream at St. Louis?

A. Yes sir.

Q. That takes into consideration the entire population, both rural and urban.

A. The total population on each drainage area of each river basin.

Q. And is based upon a population and drainage area of the respective rivers?

A. It is.

Q. I understood you to say yesterday that typhoid fever germs would live longer in less polluted water than in more highly polluted water. Is that correct?

A. That is correct.

Q. From the stand point of population and area of 12454 water shed, state whether or not the waters of the Schuylkill at Philadelphia are more greatly polluted than the waters of the Illinois, the Mississippi and the Missouri at St. Louis?

A. The pollution of the Schuylkill River at Philadelphia, based upon the area of the drainage basin and population is much more polluted than the combined waters of the Illinois, the Missouri and the Mississippi Rivers at St. Louis. Indeed the figures show that the probable pollution of the Schuylkill River by this method of investigation is about fifty per cent. greater than the pollution of the Illinois River at its mouth, and in the absence of other data the Illinois River would be regarded as a better source of public water supply than the Schuylkill River and the combined flow of the Illinois and Mississippi and Missouri would largely improve this condition with reference to the city of St. Louis, so far only as the probable sewage pollution is concerned. I would like to add to that, this investigation excludes all chemical data and all consideration of the amount of suspended matter flowing in the streams.

12455 Q. In the chart which you introduced yesterday, which is a table showing the results of experiments to determine the longevity of the bacillus typhosus in the waters of the Schuylkill and the Deleware Rivers, please state again where the samples from which these tests were made were taken?

A. The samples from the Delaware River, which was the stream really under consideration, were taken opposite Harrison Mansion at the site of the Torresdale Filter Station, at a point about ten miles north of Market Street Wharf, and from the same point that the water was taken for a period of nearly two years during the test of experimental filters with the Delaware water. The sample from the Schuylkill River was taken from the forebay of the Spring Garden Pumping Station.

Q. The tests made on October 16th or rather test number 5—how many observations were made?

A. An observation was made each day and usually three plates were made up from each sample each day. The observations were continued until no growth of the typhoid organisms

was found on the agar plates and referring to the test of
12456 October 16th, the last attempt to demonstrate the presence
of the typhoid organism in the sterilized water was
made on the fourteenth day after the observation with negative
results.

Q. Was there any tests made on the thirteenth day?

A. No, there were none. They were only made on the days shown on the table, the first, second, third, fifth, eighth, twelfth and fourteenth.

Q. None were made on the ninth and tenth?

A. No sir.

Q. Not having been made on the ninth and tenth you can not say then whether they would appear?

A. Only by inference comparing the result of the last two days of observation where some of the plates showed no marks at all, no growth at all and the others a very small number compared with the numbers found on the previous day of the tests.

Q. If the water frrom the Schuylkill and Delaware rivers
from where these samples from which those tests were made
were taken should run down the stream with no added polluting
or infecting material and should contain typhoid fever germs
state whether or not it is your opinion that all of the typhoid
fever germs would die out within eight days from the
12457 time they were deposited in that water?

A. If the water was of normal sewage pollution I believe they would.

Q. Then would you recommend the water of the Delaware and Schuylkill after it had passed down the stream for eight days from the time the typhoid infecting material was discharged into it and it received no additional infecting material as being free from typhoid fever germs?

A. I believe that it would be.

Q. Would you recommend it for domestic purposes as being free from typhoid fever germs?

A. No, I would not because there are other things than typhoid fever organisms, other pathogenic bacteria.

Q. Would you recommend it as being free from typhoid although it was found to exist at the end of eight days and no determinations were made on the ninth and tenth day while it was not found on the twelfth day?

A. Yes, I should by reason of the fact that on the eighth day referring to the test of October 16th, compared with the fifth day the numbers were so largely reduced as to suggest
12458 their total disappearance within a short time after that observation, certainly within less than a day.

Q. Why, then, was it necessary, to make platings on the twelfth and fourteenth days?

A. To set aside any doubt of the total elmination of the organism at or near the eighth day of the test.

Q. Would it not have been better and more satisfactory to have made out determinations on the ninth and tenth days?

A. I am not sure that it would. Two of the tests show no growth whatever on the eighth day. Three others show only one organism found on the plates after the eighth day. It would be a fair inference that there would be no growth thereafter, but as a precaution the test was made on the twelfth and fourteenth days and then discontinued. It will be observed that in the preparation this test was to be continued for three weeks if there was any indication of a growth for so long a time, so that the column under the twenty-second day has no figures in it whatever, upon the theory that if the organism was not found on the twelfth and fourteenth days it certainly would not be found on the twenty-second.

12459 Q. Assuming that typhoid fever germs lived in the water of the Schuylkill and Delaware eight days what effect would the addition of a double quantity of water in that river have upon the longevity of the typhoid?

A. It might have the effect of slightly prolonging the life of the organism. These tests that we are now discussing of course were made on sterilized water, and there was no other live organism in the water excepting the typhoid organism or the bacillus coli communis. I do not believe that it would live as long in unsterilized water as it will in sterilized water, for the reason that the entire food material in the latter water will be appropriated to maintenance of life of that one organism.

Q. Each organism, whether it be the typhoid bacillus or the bacillus of some other character, is independent in and of itself is it not?

A. Each has its independent life history so far as we know.

Q. What effect has the diminution of organic matter in compositions containing typhoid fever germs upon these germs, such as the addition of greater quantities of water, or by
12460 the clearing up and purification of the substance in which these germs are contained?

A. By the addition of other water assumed to be pure there would be a reduction in the percentage of organic matter, and a reduction in the total numbers of bacteria per cubic centimeter of water, but there would be no reduction in the total amount of organic matter and it would be a little difficult to predict just what would happen unless the dilution was very great. If to one quart of polluted water was added one quart of unpolluted water the amount of organic matter would be just the same and the number of bacteria the same, and they might go on and perform their operations quite the same by reason of the fact that some of the organisms of fermentation and decomposition flourish best in a strong atmosphere of oxygen. Some will not develop at all in the absence of oxygen and others will develop either with it or without it, and then there are still others that can only develop as anaerobes in an atmosphere that is devoid of oxygen, so that it would not be safe to state positively that the reduction of the organic matter and the destruction of the bacteria themselves might not be quite as great with the double volume as with a single volume, and that probably would be due to the addition of dissolved oxygen to the water by the
12461 purer water.

Q. Sewage concentrated to that extent which produces septic operations is more destructive of pathogenic bacteria than it is in any other condition is it not?

A. I think it is for the reason that the acidity of fermenting sewage is calculated to quickly destroy the more delicate organisms like the typhoid bacillus and some other pathogenic bacteria.

Q. Then as the degree of concentration becomes greater the shorter the life of the pathogenic bacteria and as the degree of concentration becomes less, the degree of sewage concentration becomes less, the longer the life of the pathogenic bacteria?

A. I think that is the true condition, that the pathogenic organisms, those that are not spore bearing, like anthrax for example, would have the shortest life in a very highly concentrated sewage.

Q. The temperature of the water has something to do does it not upon the longevity of pathogenic bacteria, in fact of all bacteria?

12462 A. It does; it has a marked influence. Those bacteria that are indigenous to water or find their normal habitat in water perish when the temperature of the water is raised even to body heat for a reasonable length of time. Upon the other hand it is doubtful if some of the pathogenic bacteria propogate freely when the water is at normal or low temperature.

Q. Mr. Hill, is it not a fact that diminution in the chemical constituents of water have a tendency to bring about conditions of that water such as will prolong the life of the pathogenic bacteria by reason of the fact that such bacteria live longer in unpolluted water than in polluted water?

A. Some of the dissolved solids in water undoubtedly contribute to the life of some of the bacteria and may have an inhibiting effect on the growth of other bacteria.

Q. As a general proposition if sufficient food and material are supplied of the proper kind what would be termed pure water should guarantee the greatest longevity to some of the bacteria?

A. It would not be true of all. In all cases, of course, it is assumed that there is food material in the water. It may be taken as a settled proposition where there is no food material that bacteria will not live.

Q. What significance does a sanitarian give to the total 12463 oxygen consumed in the chemical determination of a water?

A. That is generally looked upon as showing the relative amount of organic matter in the water. Independently considered it is not worth much, but we regard it as of value in determinations of the operation of filters, for example as showing what percentage change has taken place in the total oxygen before and after filtration.

Q. Can that be influenced by reason of an added volume of water?

A. That would have an effect upon it, and I mentioned in my testimony in chief yesterday that some consideration must be given to the fact that the average stream flow for the Illinois River was somewhat greater for the year 1900 than for the year 1899.

Q. Assume then that typhoid fever germs are deposited into a river, have these chemical constituents or determinations such as total oxygen consumed, etc., show a decrease. It is reasonable to believe is it not that the longevity of the typhoid germs contained in that water will be extended?

12464 A. The change in the chemical constituents as between two periods or tests or as between two points of observation is usually not great enough to suggest any material increase in the longevity of the typhoid organism. If the change was very great suggesting an almost complete removal of organic matter, and probable extinction of the stronger species of bacteria by reason of lack of food material to support life, and the typhoid organism was then supposed to be in such water, undoubtedly there would be some prolongation of its life by reason of the fact that the water had reached a considerable degree of purity. In that way, Mr. Jeffries, it is not possible by taking ordinary changes as between two stations in a stream or as between tests made at different dates where the changes are not great, to suggest any material modification in the opinion of its longevity.

Q. If there is any effect at all it is to increase?

A. Or you can assume a condition where you might purify by some process the water, still leaving some organic matter in it, and then import into it the typhoid germ, which would then be an element of danger. For example, we should greatly fear the inoculation of clear water basins with the typhoid or-
12465 ganism because there is still enough organic matter left in the filtered water to support some bacterial life and it would be a very serious condition if such a thing should happen.

Q. Referring now to the table introduced in evidence by

you yesterday made up from the reports of Professors Jordan, Zeit, Palmer and Burrill, as shown by Streams Examination which has been referred to in the evidence here, I will ask you if that is a table of bacterial determinations for the years 1899 and 1900 with the percentage of decrease and increase in the bacterial count? And if it does not show that the number of bacteria in 1900 from the Desplaines River at Joliet and the Illinois River at Ottawa and La Salle and Averyville, Wesley City and Pekin, immediately below the city of Peoria, this last city being immediately below the city of Peoria, if it does not show that such decrease is due to the fact of greater dilution in that stream and that the increase for the year 1900 over 1899 in the Illinois River at Havana, at Beardstown, at Kampsville and at Grafton is due to the fact that the bacteria contained in tht water is longer preserved by reason of the diluting effect caused by the discharge of Lake Michigan water to the drainage
12466 canal?

A. The fact of there being a smaller bacterial content in the water of the Illinois River at Ottawa and La Salle and at Wesley City, can probably be ascribed to the increased dilution of the water flowing in the channel of the river and partly perhaps to a greater rate of oxidation by reason of the added dissolved oxygen obtained from diluting the sewage with Lake Michigan water. I can not see clearly why this should cause an increase in the numbers at points below Pekin. In studying the table giving the bacterial content of the various waters discharged into the Illinois River and of the water of the Illinois River I thought that the increased bacterial content below Peoria was probably due to the sewage discharged at and below that point, and that it could not be connected with the increased flow of water in the Illinois River by reason of the draft on Lake Michigan through the drainage canal, because of the total numbers given in the table by far the larger percentage are the stronger and more hardy organisms of putrefaction and fermentation, organisms that would flourish only in polluted water, and some special cause of pollution must have occurred in the neighborhood of Pekin or Havana to bring about the considerable increase in numbers below that point, and this cause
12467 cannot be ascribed to the increased flow of water from Lake Michigan through the drainage canal.

Q. It cannot be ascribed to the Sangamon River as a tributary of the Illinois for the reason that the table shows that there is a decrease in bacterial count upon that river in 1900 over 1899?

A. No, I would not ascribe it to the flow of the Sangamon River.

Q. It can not be ascribed to the fact that the added volume of water producing the diluting effect has prolonged the life of the bacteria in the water?

A. I do not think this could be conceded as the cause, otherwise its effect should have been shown nearer the point of discharge of the drainage canal than Joliet. If it had been proved for the whole length of the Illinois River after receiving the discharge of Lake Michigan water to the drainage canal that there was an increased growth of bacteria, this might be assigned as the cause, but considering the fact that there seems to have been a considerable diminution in the bacteria between Joliet, Peoria and Pekin, it would be hard to ascribe the
12468 growth below Pekin to the same cause, that probably produced the diminished growth above Pekin. In other words the effect of the increased volume of water, if it had a tendency to increase the growth should have been manifested before the city of Pekin was reached in the flow of the river.

Q. I will ask you, Mr. Hill, if this table does not show that there was a greater percentage of reduction in the Illinois River from Morris to Ottawa in 1899, than there was in that river between those points for the year 1900?

A. That is true that the percentage of reduction was greatest in former years.

Q. Is it not a fact that between La Salle and Henry the increase was greater during 1900 than 1899?

A. It is slightly so.

Q. Below the city of Peoria is it not a fact that the percentage of reduction was much greater during 1899 than it was during 1900?

A. As a matter of fact, comparing the bacterial contents of the river at the various points from Havana down, the numbers were greater for the year 1900 than 1899 showing an
12469 increase in the content.

Q. Did you make any tables showing the comparative results of ammonias as shown by the Streams Examination?

A. No, I did not.

Q. Do you consider that important?

A. No, I do not because the essential conditions with reference to the nitrogen is probably shown by the nitrites and nitrates. A great number of tests can be made perhaps with greater precision on the nitrites and nitrates and are less liable to be in error, than the tests for ammonias, but aside from that the final tests of change of nitrogenous matter is shown in the numbers mentioned.

Q. Is it not a fact that the nitrate and nitrite test as shown in your table introduced yesterday shows that there has been a greater deposition of nitrogenous matter in the Illinois River than in either the Mississippi or Missouri Rivers?

A. That is true for both years under consideration, that the nitrogenous matter in the water is higher in the Illinois River than in the other rivers represented in the tables, and further that the degree of nitrification is correspondingly greater in the Illinois River than in the others.

12470 Q. What is the most fruitful source of nitrogenous matter in a running stream?

A. Sewage wastes contribute very largely to the nitrogen in the water. It can also come from decaying vegetable matter in the run off from the water shed, and probably the bulk of it may be charged to other sources than sewage.

Q. That, however, is a prolific source of such matter where a river runs through a highly or thickly populated community?

A. It is a constant source. Where the cause is vegetable detritus it does not come in to the water with the same daily regularity.

Q. Assume that typhoid dejecta of a certain city deposited into a river from which a city below obtains its water supply which produces typhoid fever in the second city mentioned or the city below, is it not a fact that the frequency of the occurrence of typhoid fever in the city below caused from the typhoid dejecta from patients in the city above is governed considerably by the temperature of the water, the stage of the water in the river, the velocity of the water and other natural conditions which affect the sanitary condition of that water?

A. It is.

12471 Q. Assume that typhoid fever germs discharged in the drainage canal at Chicago from typhoid patients in the city of Chicago reached the city of St. Louis and produced typhoid fever in that city by reason of the fact that the inhabitants of that city used the water of the Mississippi River for drinking and domestic purposes. Is it not a fact that local conditions upon the Illinois River such as the temperature of the water, variation in stream flow, etc., affect in a large measure the variations in the occurrence of typhoid fever from that source in the city of St. Louis, taking into consideration this one important fact that the variations in the stream flow in the Illinois River range from eight to twenty days?

Mr. Todd: I object to the hypothetical question on the ground that there is no evidence in this record of eight days between Chicago and St. Louis.

A. Assuming that typhoid fever organisms entering the drainage canal at Chicago may be the cause or are the cause of typhoid fever in St. Louis, then undoubtedly the temperature of the water flowing in the Illinois River, the variations in the rate of stream flow and other physical conditions in and along the river would have an influence on the resulting rates of typhoid in St. Louis. High temperature of water in the Illinois

12472 River should favor the longevity of the typhoid and other pathogenic bacteria; low temperature in the water of the river should have the opposite effect. A high current would naturally shorten the time for deposition of suspended matter in the water in travelling from Chicago to St. Louis, and a low current would have the opposite effect. The contribution of waste matter to the river along its length between the lower end of the drainage canal and the mouth of the Illinois river might contribute to the longevity of pathogenic bacteria, including typhoid, and it might have an inhibiting effect on this growth, for example the acid waste from certain factories along the stream might kill the bacteria.

Q. Is it not a fact that sanitarians are not only interested in the purification of water by filtration as a water supply but are also interested in the proposition of prohibiting pollution of water supplies?

A. They are.

Q. Is it not a fact that in various parts of the civilized world the pollution of rivers utilized as water supply is prevented although filtration plants are established?

A. It is a fact.

12473 Q. What effect will the increasing population upon the water shed have upon the subject of filtration from the standpoint of a sanitarian?

A. It will stimulate the extension of filtration because in my opinion it would be difficult to create a sentiment in the large communities of the United States at the present time in favor of such treatment of sewage as would render it innocous when delivered into running streams or lakes, and the only other remedy we now see is the filtration of such polluted waters, attempting to render them potable by this means. The time may come after filtration has been thoroughly exploited and is regarded as an established feature of water works which draw their supplies from polluted sources, and when a higher degree of purity of public water supplies is demanded, that a step will then be taken in the direction of protection from sewage pollution of streams and lakes from which municipal water supplies are now taken. At the present time, however, I do not look for any strong public movement along the line of effective sewage disposal at the hands of the larger cities, with a view of course of defending the waters of streams or lakes which are used as sources of city
12474 water supply.

Q. Will not an increased population upon a water shed have a tendency to increase precautionary measures used in the operation and construction of filtration plants and require by reason of the increased undertaking towards slower processes of filtration?

A. No, I don't think so. Our experience with the filters in Philadelphia shows that we are able to successfully maintain unusual rates of filtration with an entirely satisfactory quality of effluent, when measured by standards that prevail abroad for filtered water, provided that efficient measures are adopted to previously rough filter the water or to prepare it before it is

passed on to the final filters. There are a few cases in Europe where plain sand filters have been operated at rates in excess of three million gallons per acre per day of twenty-four hours. The two exceptions that I recall are Zurich, Switzerland, and Schiedam in Holland. In the latter place preliminary filters are used. At Zurich the water obtained from Lake Zurich is very free from suspended matter excepting Plankton. With the filters that are now in operation at lower Roxborough and other filters that have been used in the experimental investigations during the past four
years, the rates have been maintained at from six to ten
12475 million gallons per acre of sand surface per day of 24
hours without impairing the quality of the filter effluents; and as a result of the several months practical test of filters on a large scale at Lower Roxborough, and a longer test of experimental filters on the waters of the Delaware and Schuylkill Rivers the normal rate of filtration has been fixed at six million gallons per acre per day. Knowing that filter effluents at this rate are quite as good as those of lower rates adopted for similar filters now in use at Albany, New York, and elsewhere I do not think, if the source of supply is known to be polluted with sewage or is known to have a higher degree of such pollution than some other source, that this would involve an increased cost of construction or increased cost of operation. It should, of course, involve increased vigilance on the part of the manager of the filters, but this does not necessarily entail increased cost of operation.

Q. Assuming, Mr. Hill, that for several years prior to 1900, the Illinois River during the greater part of the year was a sluggish stream, scarcely any current, having a green scum for-
mation upon its surface, that when rowing in a skiff the
12476 path of the skiff could be seen for considerable distance
behind by reason of the formation upon its surface; that by throwing a chunk of wood into the water the direction in which it would travel depended altogether upon the way in which the wind would blow; that for miles above the four dams in that river there was practically no current and that since January 1900 this green scum has disappeared; that there has been a continuous current from one end of the river to the other both above and below the dams. Is it not a fact that the con-

ditions existing in the river prior to 1900 were more conducive to the destruction of pathogenic bacteria, assuming that they were contained in the water both prior and subsequent to 1900 than under the conditions which have existed subsequent to that time?

A. I do not think that is necessarily true in view of the fact that the introduction of a considerable volume of relatively pure water from Lake Michigan with a corresponding considerable increase in the dissolved oxygen in the waters flowing in the river might contribute to a more rapid oxidation of the organic matter than if it depended entirely upon the processes formerly going on in the pools formed by the dams 12477 in the river or by the formation of sand bars, a situation that would happen in a river of a very sluggish current. It is altogether possible, and this fact would depend upon the relation of the flow from Lake Michigan to the total flow of the Illinois River, and would probably be most favorable when the two volumes of water were very nearly alike, that the addition of lake water from Lake Michigan would stimulate the reduction of organic matter and with it the reduction of the bacteria. There is certainly some point between the septic conditions of slow flowing sewage in the stream, and that of a rapidly flowing stream where the self purification as you may so term it or the oxidation of organic matter will be at its optimum point, and I do not think that the addition of such a volume of water to the stream flow of the Illinois River as would produce a flow over the dams at all times would be calculated to prolong the life of the pathogenic bacteria.

Q. It is true is it not that typhoid fever germs will live longer in water that is highly oxidized than in water which contains no oxygen?

12478 A. That is true, provided there is sufficient organic matter to furnish proper food.

Q. Do typhoid fever germs require food for their subsistence in waters of a running stream?

A. It is a question whether their known longevity in water is due to food material obtained from the water or whether it is due to other causes. It is just possible that such food material as they find that may be acceptable to some extent prolongs their life, but they do not find, of course, the food necessary to propagate or multiply in water. Neither is it known that they are concerned in any of the putrefactive and fermentative processes going on in the decomposition of organic matter.

Q. With proper food supply there is no reason to say they should not propagate if the temperature is right, is there?

A. There is no evidence to show that the proper food material for the typhoid organism is found in water; on the contrary all evidence indicates that it is not found there, but it would not be safe to say that some portions of the life history of the typhoid organisms in water might not be due to
12479 the use of some food materials found in water. The fact that we can grow typhoid organisms in flasks specially prepared indicates that there is food material upon which they flourished for a limited length of time, and some such material or its equivalent may be found in water.

Q. Assuming that there is a city situated upon the Mississippi River immediately above the intake of the St. Louis water works with a population of 13,000 people in which typhoid fever is continually prevalent from one end of the year to the other, the extent of such fever being as much as is ordinarily found in a city of that size in this country, would not such a city be a danger and a menace to the people of the city of St. Lous taking their water supply from the Mississippi River immediately below the sewage discharges of said city of 13,000 population?

A. There would be, and the measure of this danger would be the population of such city stated as 13,000, its distance from St. Louis to the point of water intake and the rate of stream flow between the city and the intake.

Q. And as the population of that city increases from thirteen to one hundred and sixty thousand the danger would increase would it not?

12480 A. The danger would increase directly with the increase of population.

Q. When was the last edition of your work on water supply published, Mr. Hill?

A. 1898.

Q. What is the title of that book?

A. The Purification of Public Water Supplies.

Mr. Todd: I desire to prove at a latter date that Jefferson City, Missouri, is a sewered town and sewers in the Missouri River, unless it is admitted.

With the above reservation the defendants, the State of Illinois and the Sanitary District of Chicago, rest their case.

Adjourned subject to notice.

JAMES W. HILL.

12481 Room 282, Southern Hotel, St. Louis, Mo. 10:00 a. m., Monday, May 23, 1904.

Continuation pursuant to agreement for complainant's rebuttal evidence.

Present, the Commissioner and Hon. S. B. Jeffries representing complainant, and James Todd, Esq., representing defendants.

DR. EDWARD W. SAUNDERS,

a witness called on behalf of the complainant in rebuttal, being duly affirmed by the Commissioner, testified as follows:

DIRECT EXAMINATION, by Mr. Jeffries.

Q. Doctor, what is your profession?

A. Physician.

Q. Where do you practice your profession?

A. In St. Louis.

Q. You reside in St. Louis?

A. Yes, sir.

Q. How long have you practiced in St. Louis?

A. Twenty-six years.

Q. What schools of medicine did you attend?

A. The University of Virginia.

Q. When did you attend this school?

A. I graduated in 1875.

Q. What has been the character of your practice, Doctor?

12482 A. General practice.

Q. What is the street number of your office now?

A. 3003 Lafayette avenue.

Q. Are you acquainted with the disease known as typhoid fever?

A. Yes, sir.

Q. Have you treated that disease?

A. Yes, sir.

Q. Or patients afflicted with that disease?

A. Yes, sir.

Q. Are you acquainted with what is known as the Widal test?

A. Yes, sir.

Q. As a professional man, Doctor, what is the real object and use of the Widal test?

MR. TODD: I object to the question on the ground it is not rebuttal and has already been gone into in chief by the complainant, and for the further reason it is incompetent, irrelevant and immaterial.

A. Well, it is to assist the physician in making an early diagnosis of typhoid fever.

Q. What advantage is this early knowledge as to the character of the disease in the treatment that is given typhoid patients?

12483 A. It enables a physician to treat it very much more effectively.

Q. Is it of any assistance to the physician in preventing the disease becoming fatal in the particular patient?

A. Yes, sir.

Q. This Widal test is used for the discovery or rather to ascertain whether or not the patient is afflicted with typhoid, is it?

A. Yes, sir.

Q. State, Doctor, whether or not it is used for determining the cause of death or only in the aid of making the early diagnosis of the disease.

A. I should say only in making an early diagnosis of the disease, practically. It might be used for determining the cause of death, but practically, I should say, for making an early diagnosis.

Q. When patients die of typhoid fever, is it ordinarily necessary or general for the attending physician to use the

Widal test for determining whether or not death was caused from that disease?

A. No, sir.

12484 Q. What influence has this test had upon you in your practice in making out death certificates to the health department of the city of St. Louis?

MR. TODD: Object to the question for the reasons stated in my previous objection, to a previous question.

A. None at all, I think.

Q. You have treated cases of typhoid fever in your practice in St. Louis?

A. Yes, sir.

Q. State whether or not you have been called in consultation with reference to diseases of this character?

A. Yes, sir.

Q. State whether or not these consultations were frequent or infrequent?

A. Well, I should say—it is rather hard to answer the question at all. You mean in the course of a year?

Q. During the last seven or eight or ten years of your practice?

A. I should say quite often.

Q. Are you acquainted with your profession or with the members of your profession in St. Louis, generally?

A. A large number of them, yes, sir.

12485 Q. Do you know whether or not the Widal test is in general use by the profession in St. Louis?

MR. TODD: I object to the question for the reason that it is incompetent, irrelevant and immaterial.

A. I consider that it is.

MR. JEFFRIES: I suggest to the court that the counsel has lost sight of the testimony of Dr. Barker, Dr. Thayer and Dr. Dock.

MR. TODD: In reply to counsel's suggestions would state that defendant's counsel's vision is very clear upon the testimony of these men and it is not competent for this witness to tell what other witnesses are doing as it would be mere hearsay and therefore incompetent.

MR. JEFFRIES: I suggest that the whole of Doctors Barker, Dock and Thayer's testimony was as to what other men had done and for that reason counsel must be bound by his own statement.

A. Yes sir, I consider it so.

Q. How long has this test been in use in St. Louis?

A. I can not answer that question with any certainty,
12486 but I should say about six or seven years.

Q. As a professional man and knowing the profession as you do, state what effect if any the Widal test has had upon the profession in signing and making out death certificates to the mortuary office of the health department?

MR. TODD: Object to the question for the reasons heretofore stated in my previous objections.

A. I should say that it has taken a number of cases from the typhoid list, and added a number to it, because cases of nondescript fevers which before that time were assigned to the malarial list after that were assigned where they properly belonged, to the typhoid. On the other hand, there were quite a conglomeration of cases, patients dying in what the older writers called the status typhosus, or the typhoid state, which typhoid state had nothing to do with true typhoid fever, and these cases were taken out of the typhoid list.

MR. JEFFRIES: Q. State whether or not the Widal test or any other practice has resulted in taking from the malarial list and placing them in some other list besides typhoid?

A. I hardly think so.

12487 Q. State whether or not some deaths supposed to be
malarial have not failed to react under the typhoid test and therefore have been placed under some other head?

A. You mean deaths?

Q. Yes sir?

A. I will answer that by saying I can conceive of a case where a physician has treated a case for malaria and sees death approaching and makes the Widal test and finds it is not typhoid and that leads him to make a more careful examination and finds the patient is dying of nephritis or something he had not found before. Yes, I can conceive of that case occurring.

Q. So then in that event the death would be reported as nephrites instead of malaria or typhoid?

A. Yes sir.

Q. Under such cases prior to the Widal test, the death might have been reported as caused by malaria?

MR. TODD: Object to the question as this witness is not competent to pass upon what might be done by some other physician of a different standing than himself and as purely
12488 speculative and incompetent, irrelevant and immaterial,
and not rebuttal of anything that has been put in by the defense in this case.

A. It seems to me that this question only bears out what I said before, that the Widal test has conduced to the accuracy of the diagnosis, and in that way has taken a number of deaths out of the typhoid list that heretofore was under the head of typhoid before the introduction of the Widal test.

MR. JEFFRIES: Q. So that these cases of malaria to which you referred in your previous question, and the attending physicians finding death approaching, and failure of the reaction of the Widal test taking place it resulted in keeping that death out of the typhoid list which might otherwise have found place there?

A. Yes sir.

Q. I understand you to say then that since the Widal test has come in vogue, where patients believed by the attending physician to be afflicted with malaria and finding death approaching have applied the Widal test which has resulted in the death being recorded under some disease other than either malaria or typhoid?

12489 A. Yes sir.

Q. What in your opinion has been the effect of the Widal test upon the relative number of deaths from typhoid fever in St. Louis since its use, as compared to the same period prior to the use of such test by the physicians in St. Louis?

A. I am not able to answer that question because I have no clear idea in my own mind as to what number have been taken out of the typhoid list and what number have been added to it by the test.

Q. Doctor, taking into consideration the value of the Widal test in making an early diagnosis of typhoid fever, and taking into consideration the fact also that it is a disease, which, if properly treated in its early stages, is less likely to become fatal, what, in your opinion, has been the effect upon the typhoid mortality in St. Louis since its use as compared with conditions existing prior to its use?

A. The relative mortality?

MR. TODD: Object to the question for the reasons heretofore stated.

MR. JEFFRIES: Q. Yes.

A. Relative to the number of cases?

12490 Q. Yes sir?

A. I should say very favorable.

Q. By that you mean what?

A. That a given number of cases occurring since the Widal test will afford a much better mortality rate than the same number of cases occurring before the Widal test.

Q. What, then, would be the effect of such test upon the total number of deaths occurring from typhoid fever in St. Louis?

A. It would be favorable.

Q. Assuming that all conditions were similar, both subsequent to the use of the said test, as existed prior thereto, how would the conditions compare with reference to the mortality record from typhoid fever?

MR. TODD: Object to the question for the reasons heretofore stated.

A. Assuming all other conditions tending to recovery were the same, those in which the Widal test is used for an early diagnosis are found to show a better mortality rate.

MR. JEFFRIES: Q. Then if conditions, locally and other-
wise for counteracting the disease are the same, that
12491 period of the time during which the Widal test is em-
ployed in the early stages of the disease would show a
better mortality record from typhoid fever than that period
when such tests are not employed?

A. Yes sir.

MR. TODD: Object to the question for the same reasons heretofore stated in my objection.

MR. JEFFRIES: Q. State whether or not there is such a thing as trichinosis or other similar diseases which resemble typhoid and which might be confounded with, and deaths from which might be reported as typhoid were it not for the Widal test?

A. Yes sir.

Q. Such diseases, without the use of the Widal test, might be confounded with typhoid?

A. Yes sir.

Q. And without that test having been employed, during sickness, if death occurred it might be reported as typhoid?

A. Yes sir.

Q. But with the use of the test it would not be reported
12492 as typhoid?

A. Yes sir.

Q. Doctor, did you receive any circulars from the time of the opening of the drainage canal from the board of health or any one connected with the board of health urging you to report all cases of typhoid to them?

A. I think I did. I am not sure about the time, but I remember receiving a circular with reference to reporting typhoid fever.

Q. Do you know whether that circular was received generally by the profession?

A. I do not know whether it was or not. I suppose it was.

Q. Did you hear the circular discussed by the members of your profession?

A. No sir.

Q. What effect has the fact that you had received such circular had upon you in reporting cases of typhoid to the health department?

A. Cases or deaths?

Q. Deaths?

A. None at all.

12493 Q. Were you in any way influenced in your action in making such report by receiving these circulars?

A. No sir, I never thought of it in that light. It never occurred to me that was the object of it.

Q. Did you ever hear the profession discuss the object of those circulars?

A. No sir, I never did. I do not think it ever occurred to any of them.

MR. TODD: I move to strike out the last part of his answer as not competent to what might have occurred to some body else. If it did not occur to him it is a matter that he is not competent to pass upon.

MR. JEFFRIES: Q. Were you in a position to have heard any such discussion had it taken place?

A. Yes sir.

MR. TODD: Object to that question as incompetent, irrelevant and immaterial, and not rebuttal.

MR. JEFFRIES: State, doctor, whether or not in your opinion any of the physicians in St. Louis have been in any way influenced by reason of having received these circulars, 12494 about the time of the opening of the drainage canal or any other time?

MR. TODD: Objected to as incompetent, irrelevant and immaterial.

A. I think not.

MR. JEFFRIES: Q. State whether or not, in your opinion, physicians generally have been influenced by these circulars to report a greater number of deaths from typhoid fever than they would have otherwise reported as due to that disease in the event such circulars had not been sent out by the health department?

A. I think not.

Q. Do you remember the occurrence of the opening of the drainage canal?

A. Yes sir.

Q. State what effect, in your opinion, the opening of the drainage canal at Chicago, thence in the Desplaines and thence in the Illinois river, had upon the physicians of St. Louis, in making the reports from deaths from typhoid in St. Louis?

MR. TODD: Object to the question as incompetent, irrelevant and immaterial.

A. I have no reason to think it would influence them.

12495 MR. JEFFRIES: Q. Assume that a physician certifies that one of his patients died of congestive fever, what would you understand by that term?

A. I would not have any clear understanding of the case at all. I would not know what it meant.

Q. Would it necessarily mean typhoid fever?

A. Not necessarily, no sir.

Q. Might it mean anything else besides typhoid fever?

A. Yes sir. Yes, it might. I do not know really what a man would mean by it. I have really no clear conception.

Q. Should a physician certify that one of his patients died of typho malaria, what would you understand by that term?

A. I would understand that he died of typhoid complicated with malaria.

Q. If a case be reported as remittent fever, what would you understand by that term?

A. I would suspect that he died of typhoid because indigenous remittent fevers are not fatal.

Q. Has the age of the patient anything to do with passing judgment upon that point? 12496

A. Ye sir.

Q. What effect has the age of the patient upon the making of the determination?

A. Malarial fevers do carry off the very young and the very old.

Q. Suppose that a remittent fever patient died in infancy?

A. Then I would believe that that was the true cause of death.

MR. TODD: If he died of remittent fever, you would assume that that was the true cause of death?

A. If the infant patient died in convulsions at the onset of the attack, but not if it died after a protracted illness inasmuch as quinine is a specific remedy for all malarial fevers of this locality, and only those taken off such as the very young, in convulsions, or the old in the first onset, those that are liable to be taken off by that cause.

MR. JEFFRIES: Q. State whether or not the same would be true with reference to intermittent fever?

12497 A. Yes sir.

Q. How about bilious fever, doctor?

A. I have no more clear conception of bilious fever than I have of a congestive fever.

Q. Is the same true with reference to malaria and simple continued fevers?

A. The same is true of malaria, but of simple continued fevers I would say that they were all in the typhoid class.

Q. Unless the patient be an infant?

A. Well, no, I would not even make that qualification, for the reason that a fever which continues any length of time, if it be malaria, is amenable to quinine and if not amenable to quinine I believe in the Osler dictum that any fever that continues a week and is not amenable to quinine and is not anything else, is typhoid.

Q. Might it not be something else besides typhoid?

A. The simple continued fever, do you mean?

Q. Yes sir?

A. In speaking of deaths?

Q. Yes?

12498 A. I hardly think so.

Q. Do infants and old people often die of typhoid fever, doctor?

A. No sir.

Q. At what age are persons most likely to have typhoid fever?

A. Young adults.

Q. At what seasons of the year is typhoid fever most prevalent in St. Louis?

A. In the latter part of the summer and fall.

Q. And it is more frequent in the summer and fall than in the winter or spring?

A. Yes sir.

Q. Doctor, state whether or not you have observed more or less typhoid within the winter and spring months within the last few years than formerly in St. Louis?

MR. TODD: Object to the question as it is not rebuttal as this whole subject was gone into in the plaintiff's case in chief and is therefore incompetent, irrelevant and immaterial.

A. I have.

12499 MR. JEFFRIES: Q. Doctor, do you remember a typhoid condition in St. Louis in 1892 and 1893?

A. Yes sir.

Q. What were those conditions?

MR. TODD: Object to the question as it is not rebuttal and has been fully explained by Dr. Ravold as a year of spring epidemic and has not been contradicted by the defendant in the case.

A. Severe epidemic.

MR. JEFFRIES: Q. Was it general over the city, or localized?

A. It was pretty general.

Q. Do you remember any epidemic since that time?

A. Yes sir, I remember one in the fall of 1899, just before the opening of the canal.

Q. Was that general over the town or local?

A. That was local.

Q. Where were those cases mostly?

A. In the west end, the better quarters of the city.

12500 CROSS EXAMINATION.

By MR. TODD:

Q. Doctor, are you connected with any institution of medicine in St. Louis?

A. Yes sir, the medical department of the Washington University.

Q. How long have you been connected with that department?

A. Since the consolidation of the Missouri Medical with the Washington University.

Q. What branch of medical science do you teach?

A. I teach diseases of children and clinical obstetrics.

Q. In the diagnosis of typhoid fever do you regard the Widal test as the only true test?

A. No sir.

Q. May not a patient have typhoid fever and yet the doctor fail to get the Widal reaction?

A. Yes sir.

Q. In order to properly diagnose typhoid fever it must be based upon the totality of the symptoms?

A. Yes sir.

Q. How many doctors in the city of St. Louis are practicing medicine?

12501 A. I think the last report is some sixteen hundred. I am not accurate about that.

Q. How many of those doctors have you a personal acquaintanceship with?

A. I do not know.

Q. Well, approximately?

A. Well, now, I really could not approximate it.

Q. Ten per cent.?

A. That would be one hundred sixty. Yes sir.

Q. Twenty per cent.?

A. Yes sir, I should say so.

Q. This acquaintanceship which you have with the number of doctors would not exceed twenty per cent., would it?

A. I could not state that whether it would or not. Really, I do not feel that without a careful computation—if I had the list before me, the catalogue, I could tell you in half an hour just how many I do know.

Q. Well, assuming—I am not trying to bind you by a definite answer on this proposition, but the purpose of what I want is to inquire the acquaintanceship which you have with the doctors in St. Louis—is that an acquaintanceship which extends to the bedside of the patients which they treat, 12502 and their methods of diagnosis?

A. With all of them?

Q. Yes sir?

A. No sir.

Q. The doctors that you have an intimate acquaintanceship with their method of treatment of diseases, are those you are called in consultation with?

A. Yes sir.

Q. What per cent. of the doctors would you be called in consultation with?

A. You mean at any time?

Q. During the year.

A. Or during my whole profession?

Q. Take it by the year, an average of the year, say?

A. How many in a year that I would be called in consultation with?

Q. Yes, just generally, doctor?

A. You do not mean how many consultations a year, but how many different physicians?

Q. Different physicians?

12503 A. Well, I will just venture a guess. I should say from fifty to one hundred.

Q. How many cases of typhoid fever do you treat in a year, on an average?

A. I could not answer that question without looking it up.

Q. Approximately?

A. Without looking up my records.

Q. Approximately—could you give an approximation?

A. You mean by treating, that I treated and saw in consultation all together?

Q. Yes sir?

A. That I have seen?

Q. Yes sir?

A. Well, I should venture, just as a guess, the nearest approximation that I could make, I should say from thirty to fifty, or some where along there.

Q. What percentage of those that you have seen are fatal cases?

A. Well, inasmuch as I see some of them in consulation and in a very bad condition, I see perhaps a larger mortality that would seem proper, but the percentages of mortality in cases that I see would bear no ratio to the percentage of mortality in typhoid fever in the city. I remember seeing
12504 two deaths in two hours, from hemorrhage.

Q. Out of thirty cases of typhoid fever, assume that that approximates the number of cases treated by you, in consultation and otherwise, would there be as many as ten deaths during the year?

A. Well, sir, I should say outside of that that I saw three in consultation in one afternoon. That was during the last epidemic.

MR. JEFFRIES: Q. In 1899?

A. Yes sir, in 1899. I should say that I saw anywhere from two to three or four or five deaths in a year.

MR. TODD: Q. What importance do you attach to the Widal test?

A. I think it is a very valuable means of diagnosis.

Q. Of the 1,600 doctors practicing medicine in the city of St. Louis, how many of those doctors are homeopaths?

A. I have no idea of that. I never looked it up.

Q. There are quite a number of homeopathic physicians in town?

A. Yes sir.

Q. Do you know whether they employ the Widal test or
12505 not?

A. I do not know.

Q. What is your opinion as to whether the sixteen hundred doctors in the city of St. Louis are employing the Widal test?

A. Well, I do not know whether the homeopathic doctors employ it at all. You mean outside of them?

Q. Outside of the homeopaths?

A. Well, I should say that all of them, if they are in doubt, would be liable to appeal to the Widal test in a case.

Q. Do physicians, as a general proposition, the ordinary physicians, and I assume you have those in St. Louis?

A. Yes sir.

Q. Do they employ the Widal test?

A. I think they do, yes sir. Whenever they are in doubt they do.

Q. Well, are there not some physicians here that are never in doubt?

A. Yes sir, that is right.

Q. All of these sixteen hundred physicians are not experts on typhoid fever, are they?

A. No sir.

Q. Are you acquainted with the board of health statistics of the city of St. Louis, the board of health mortality sta-
12506 tistics of the city of St. Louis?

A. No sir, I have not looked at them for some time.

Q. If it should appear in the board of health statistics of the city of St. Louis during the last ten years that they have a group of deaths reported as remittent, intermittent, typho malaria, congestive and simple continued fever, and that those deaths amount to something like 200, would that be any reflection upon the doctors of St. Louis in their diagnosis of diseases of that character?

A. Read the list, will you, of diseases, just the list of diseases.

Q. Remittent, intermittent, typho-malaria, congestive and simple continued fevers?

A. Yes sir, I think the number is a reflection on the diagnosis.

Q. And does not the number of deaths so characterized in the board of health report reflect upon the diagnosite ability and carefulness of the doctors who make those reports?

A. Yes sir.

Q. And if the number of deaths appearing in the typhoid death column, and the number of deaths appearing in the
12507 remittent, intermittent, typho malaria, congestive and simple continued fever column were about the same, what value would you attach to the statistics as giving evidence of the typhoid condition in St. Louis, based upon the typhoid fever death column, as they appear in those statistics?

A. Well, I should say that the majority of those cases belonged in the typhoid column.

Q. Would you say that the doctors in St. Louis were employing the Widal test generally if such a condition obtained as evidenced by the compilation of the board of health of the city?

A. At present, you mean?

Q. During the last six or eight years?

A. Since the Widal test?

Q. Yes sir?

A. No sir, I should say they were not.

Q. Is it not a fact that these practitioners wedded to the calomel and quinine are obstinate in acepting new treatment for diseases?

A. That is the tendency.

Q. And does not that manifest itself in the health statistics of the city?

12508 A. Do I understand you to say that the deaths are about equal here in typhoid and in all these others?

Q. Approximately.

A. Approximately. Yes, that proves it; they do not.

MR. JEFFRIES: I move to strike out the answer and the question for the reason that the column known as typho malaria, intermittent, remittent, congestive and simple continued fever, not only contains deaths from such diseases, but other diseases as evidenced by the fact that in the health report the persons who compiled it have placed other deaths in that column and that the question is not fair, and all statements based thereon incorrect, can not be relied upon, because the column itself calls attention to the fact that deaths from other diseases are placed therein.

MR. TODD: In reply will state that the witnesses on the side of the complainant in this case, especially the epidemiologists, predicated their argument that the drainage canal was responsible for the typhoid condition in the city of St. Louis
upon the board of health reports of the city of St. Louis,
12509 and that the injury which St. Louis sustained by virtue
of the opening of the drainage canal was manifest in the board of health reports in the city of St. Louis, and there has been no other evidence offered in this case to sustain the claim except that of the board of health reports of the city of St. Louis.

MR. JEFFRIES: In answer to the counsel, I will state that we accept the truthfulness of what is shown in the board of health reports from the deaths from typhoid fever, but that such deaths contained in the published board of health reports is the only statistics that were offered by the plaintiff. I suggest also that the counsel himself has used the columns with reference to the remittent, intermittent, congestive and other diseases and was introduced by him and not by the complainant, and that the column so introduced by him especially calls attention to the fact that deaths from other diseases are included therein.

MR. TODD: In reply counsel for defendant admits the truth of every word counsel has just uttered, but complains that complainant should have offered the remittent, intermittent,
typho malaria and congestive fever columns in order to
12510 arrive at a correct conclusion as to the typhoid condi-
tions in the city of St. Louis, and complainant's failure to do so can not militate against defendant having done what counsel charged us with having done.

MR. JEFFRIES: I will state for the benefit of counsel that the complainant did not introduce in evidence the published report of the board of health wherein the statement is made that certain number of deaths occurred each year under the head of remittent, intermittent, typho malaria, congestive and simple continued, because it would have been unfair and would have misrepresented the fact, that colmun stating and calling attention to the fact that other diseases were included therein.

MR. JEFFRIES: I object to the question for the reason the witness has stated he is not acquainted with the health statistics as made up by the health department for the last few years.

MR. TODD: Q. Assuming that the mortality health reports of the city of St. Louis disclose the number of deaths from remittent, intermittent, typho malaria, congestive and
12511 simple continued fevers during the last ten years to be
about equal to those of the typhoid deaths, is there, in your opinion, any more integrity in the reports of the physicians as to the typhoid deaths than there would be upon the remittent, intermittent, typho malaria, congestive and simple continued fever death columns?

MR. JEFFRIES: Object to the question for the reason it is for the court to determine as to the integrity and not for this witness.

A. Well, that is a hard question to answer. I would say perhaps the typhoid column is as inaccurate as the other column. That is just a guess or opinion.

MR. TODD: Q. If the typhoid column is as inaccurate as the other column, to what do you attribute the inaccuracies?

MR. JEFFRIES: Object to the question for the reason that the published report of the board of health is not compiled by the physicians who make the report, and therefore such facts are not competent to use in passing upon the credibility and integrity of the physicians in St. Louis.

MR. TODD: If counsel eliminates the board of health
12512 reports of the city of St. Louis in this case as being in-
competent, then the entire case of complainant has failed, as I am ready to show to the court.

MR. JEFFRIES: I will state to counsel that the board of health reports as published shows on its face what it represents but that counsel is imposing upon his own good judgment when he undertakes to assume that under the column of intermittent, remittent, etc., there are not deaths included which have occurred from other diseases.

MR. TODD: In reply, counsel for defendants will state that he assumes nothing that can not be found in the board of health reports of St. Louis, and makes no assumption as to its accuracies, for the defendant will not be bound in this case by any such reports that have been characterized in the manner that counsel has characterized them in his previous arguments this morning to my question.

Q. Question read.

A. To failure in diagnosis.

MR. TODD: Q. Do you recognize, doctor, intermit-
12513 tent, remittent, typho malaria, congestive and simple continued fevers, as distinct types of the disease?

A. I would say that what is generally called intermittent fever in medical nomenclature and in the nomenclature of the boards of health, is a malarial fever characterized by the presence of a certain organism in the blood. I would say that remittent fever is also a malarial fever characterized by the presence of a different organism in the blood.

I would say that typho malaria fever is a typhoid fever complicated by the presence of a malarial organism in the blood.

I would say that as to congestive fever, I do not know what that means. I do not know what a man means when he uses that term, and simple continued fever I would say that that nobody knows what that is, but it is not supposed ever to be fatal.

Q. Is it not a fact that intermittent, remittent and simple continued fevers are characteristic of malarial or typhoid and are not distinct types of fever in themselves, so recognized by clinicians and diagnosticians?

12514 A. The characteristics of malaria or typhoid?

Q. Yes sir.

A. Well, I would say that intermittent and remittent fevers are now a days recognized as characteristic germs of malaria.

Q. Are remittent, intermittent, typho malaria, congestive and simple continued fever recognized by the leading authorities, such as Osler, Welch and other men of equal standing, as distinct types of disease today?

A. Well, I would say some of them are not recognized in the sense of being types of disease apart from the organism.

Q. They are terms that have grown up?

A. Yes sir.

Q. And have been employed by physicians of the past, but are not today employed by the advanced schools in medicine in the United States and Europe, are they?

A. That is true.

Q. Malarial fever differs from typhoid fever in what way?

A. Malarial fever is a fever caused by the presence in the blood of a parasite, a malaria parasite of which there are
12515 two well recognized species in this country, and typhoid fever is caused by the introduction into the organism of the typhoid bacillus.

Q. Is there any difficulty among competent physicians to diagnosticate a case of malaria by the use of the microscopic?

A. Yes sir, there is.

Q. And other means?

A. Yes, there is some difficulty.

Q. That requires a good deal of skill?

A. Yes sir.

Q. Are the doctors in the general practice in the city of St. Louis possessed of that degree of skill necessary to make that diagnosis?

A. No sir.

Q. That is true of typhoid fever, is it not?

A. Yes sir, it is true of typhoid fever.

Q. So that in diagnosing malaria and typhoid fever it requires an expert knowledge on the part of the diagnostician to correctly differentiate those fevers, does it not?

12516 A. Yes sir, in a great many cases. I would not say in all.

Q. And that knowledge is not possessed equally by the physicians in the larger cities, such as St. Louis?

A. That is true.

Q. And that is true of other cities?

A. Yes sir.

Q. Does not the fatality of typhoid fever depend largely upon the amount of poison taken into the system by the patient that has it?

A. Yes sir. You mean by poison—you mean the germs?

Q. Yes sir?

A. Yes sir.

Q. The nearer the source of infection, the more dangerous the disease, is that not true, rather than the early diagnosis of the case of typhoid?

A. Well, I hardly know how to answer that question, Mr. Todd. Of course, if you mean geographically nearer the source of infection.

Q. No, point of time?

12517 A. I am not competent to answer that question.

MR. JEFFRIES: I move to strike out the question for the reason that the defendant's own experts on the stand testified that it is not a question as to the remoteness of the source from which the germ diseases came from, that it depends largely upon the resistant forces of the system of the patient into which the germs of disease were taken, and that the question of remoteness was considered only upon the probability or improbability of the germ being virulent or taken into such system.

MR. TODD: The evidence which counsel quotes is before the court for the court's consideration, and it is not necessary for me to construe it.

MR. TODD: Q. Would the fact that a patient was known to have typhoid fever at the beginning of the disease by the Widal test be any security against the mortality of that patient provided he was treated by a competent physician?

A. Yes sir, it would.

Q. Assume that the other symptoms of the disease, such as the rose spots, the enlargement of the spleen, epitaxis, and the other well known symptoms were present before the Widal
test was made, would the fact that these symptoms were
12518 supplemented by the Widal test change the treatment?

A. No sir, not at all.

Q. The fatality of the disease in the hands of an expert physician depends largely upon the resistance of the patient as well as the amount of typhoid bacilli carried into the system of the patient does it not?

A. Yes sir.

Q. When was the Widal test generally introduced into St. Louis?

A. I can not speak accurately on that question, but somewhere in the late 90's.

Q. Not to exceed six years ago, would it be?

A. No, I don't think so.

Q. What value would you attach to the statistics of the health department of St. Louis, in regard to its typhoid fever condition prior to six years ago, assuming that those statistics are based upon the diagnosis of the physicians of St. Louis.

A. Well, I think they can be taken to represent fairly the presence of typhoid fever. There are a great many
12519 errors undoubtedly.

Q. If it should appear that prior to six years ago they were more or about equal remittent, intermittent, typho malaria, and congestive fever deaths in St. Louis than typhoid death rates, would the death rate column fairly represent the typhoid condition in your opinion, excluding the year of special epidemics?

MR. JEFFRIES: Objected to because it is a repetition.

A. No sir.

MR. TODD: Q. Do you know of any case where a physician treated a case of malaria fever and after the treatment of that case made the Widal test and failed to find the Widal reaction, and then diagnosticated the case as some other disease before death?

A. I do not know of any such case, no sir.

Q. If the patient had malarial fever, in the hands of an expert physician, would he not be able to diagnose that case properly as malaria?

12520 A. I think so.

Q. Do you know of any case that came under your observation where the malaria parasite has been found in the same patient with a typhoid bacilli?

A. Yes sir, I have had two such cases.

Q. And respond to the Widal reaction?

A. Yes sir. Well, in one of them it responded to the Widal and the other one died of what I knew, as well as I could know, of what was typhoid, and had the malarial parasite. That was before the Widal test. The other was since the test of the Widal, and had both.

Q. Those cases are exceedingly rare, are they not, doctor?

A. They are rare, I should say, yes.

Q. And the fatality from those cases are rare, too, are they not?

A. Really, I could not say from personal observation. I can say what Professor Flint says in his book, that hopeful cases of typhoid are lost through malaria not being recognized in the late or convalescent stages.

12521 Q. But the number of deaths from typho malaria is a
very small number as compared with typhoid fever?

A. Yes sir.

Q. How does the fatalty from malaria fever compare with typhoid fever, in your practice?

A. In my practice, well I do not think that I have ever written a death certificate from any sort of malarial fever except in the very young when a convulsion carried off the patient in the onset, or in the aged where malaria carried off a very weak person. I do not believe I have otherwise made a single death certificate.

Q. In a case, such as you have just described, the old and the young, would you assign the cause of death as malaria?

A. Under what conditions?

Q. The old or the young?

A. Either of those symptoms?

Q. Yes, as the primary cause?

A. In the very young I would put it down as convulsions,
probably, or if I found the plasmodia before death as
12522 caused by malaria.

Q. Have you studied the statistics of the board of health of St. Louis since 1900, the date of the issuing of the circular?

A. No sir, I have not even looked at the items before.

Q. Assume that a circular should have been sent out from the board of health of the city of St. Louis to all of the sixteen hundred local practicing physicians, and assume also that the public press was discussing the question and the effect of the drainage canal upon the water supply of the city of St. Louis, and assume that the remittent, intermittent, typho malaria, congestive and simple continued fever columns immediately decreased during the three years and the typhoid column increased, would the effect of such an increase be manifest in the statistics of the board of health, in your judgment.

A. Well,—

Q. Assuming what I have stated to be true.

MR. JEFFRIES: Object to the question for the reason it is a conclusion that the court may draw from the facts introduced in evidence, and is not competent expert testimony from an opinion by the witness. Objected to for the further 12523 reason it assumes that the public press and the public mind was in an agitated condition upon the opening of the drainage canal which fact has not been proven in evidence, and which is not true.

Q. Question read.

A. If those are all the facts upon which I am to base a judgment, I would say yes. I do not know that I have all the facts.

MR. TODD: Q. Did you ever receive a circular of that kind prior to the opening of the drainage canal from the board of health of the city of St. Louis?

A. I have received circulars urging me to report typhoid fever I think, with other diseases, to awaken our minds to the importance of reporting those cases, but I do not remember ever receiving one in which it treated of typhoid alone, assuming that this did treat of typhoid alone. I do not say that it did for my memory is not accurate.

Q. While a circular of that kind would not have any effect upon you, doctor, because you always, I assume, reported your cases correctly, based upon your great experience in diagnostic work, are you prepared to say that it would not have any 12524 effect upon these doctors who had been diagnosing cases as trichinosis and other diseases?

MR. JEFFRIES: I suggest it could have no effect upon such fellows referred to in the question if the statement of counsel was true, physicians were dishonest and were attempting to make a concerted move towards securing a showing of more typhoid deaths occurring in St. Louis subsequent to the time of receiving the circular and prior thereto, and there is no evidence of such fact before the court.

MR. TODD: In reply will state that it is not a question of dishonesty, inasmuch as it is a question of ignorance that is responsible for the health statistics showing deaths from remittent, intermittent, typho malaria, congestive and simple continued fevers, and that a physician may be ever so honest and yet at the same time make wrong diagnosis not only at the peril of his patient, but to such an extent as to destroy the integrity of the sttatistics.

MR. JEFFRIES: If it is a question of ignorance solely I suggest that the fact of receiving the circular does not or would not eradicate the failure of any ignorance that existed 12525 upon their part after receiving the circular as well as prior thereto and that the reports would be, if incorrect, as incorrect subsequent to as prior thereto, based upon the question of ignorance alone.

MR. TODD: If that condition that counsel speaks of is true, it is a matter for the board of health of the city of St. Louis and not for the defendant, as we are not bound by any such conditions.

MR. TODD: Q. Doctor, what is trichinosis?

A. A disease characterized by a parasite taken in with uncooked or partly cooked pork, causing a diarroherea and even in severe symptoms the trichina migrate in the system and sometimes death.

Q. How many cases of trichinosis would you estimate to be in the city of St. Louis a year?

A. I do not know. I have never seen one.

Q. How many cases of trichinosis do you know of as being treated by the doctors of your acquaintance in the city of St. Louis?

A. I only know of one family a good many years ago.

12526 Q. That is an exceedingly rare disease, is it not, doctor?

A. Yes sir.

Q. And in order to guard against that disease the United States Government has an expert stationed at all the slaughter houses in St. Louis to inspect the meats?

A. Yes sir.

Q. Foreign governments have men here for that purpose?

A. Yes sir.

Q. And is there any difficulty in determining meat that is infected with trichina, by an expert specially selected?

A. No sir.

Q. So that the amount of disease, the number of deaths from trichina in the city of St. Louis would be so small that you would not consider it as an element of mistaken diagnosis of typhoid fever would you?

A. From my present statement, together with my present knowledge I would so say. I have never gone into an investigation, but that is just my experience without any investigation.

Q. Your experience is the common experience of the physicians? Your experience is the common experience of the physicians with whom you are associated, is it not?

A. Yes sir.

Q. You stated that you were acquainted with the epi-
12527 demic in the fall of 1899. Is your acquaintanceship with
that epidemic sufficient to enable you to state what the cause of that epidemic was?

A. I never came to any conclusions about it at all.

MR. JEFFRIES: Q. When you say the Government has their inspectors stationed at St. Louis, you mean to inspect the live stock coming into the slaughter pens?

A. Well, after the slaughtering I understand the meat has to be submitted to them.

Q. But the cured meats that are sent away are not inspected by the government here?

A. Brought from elsewhere?

Q. Any where?

A. No sir.

Q. And what kind of meat is more likely to contain this trichinosis?

A. Pork.

Q. Cured pork?

A. Fresh pork.

Q. Fresh pork?

A. Yes sir.

12528 MR. TODD: Q. Doctor, is it not a fact that the govern-
ment inspector not only inspects the cattle and the hogs or the hogs bought and in the slaughter houses, after the hogs are split open?

A. Yes sir.

Q. And before they are permitted to go into the cold storage and inspected, and whenever they find a hog that is diseased they put a tag on it that throws it out?

A. That is what I understood. I never saw it.

E. W. SAUNDERS.

12529 DR. WASHINGTON E. FISCHEL,

a witness called on behalf of the complainant, being duly sworn by the Commissioner, was examined in chief by Mr. Jeffries, and testified as follows:

Q. Doctor, state your name?

A. Washington E. Fischel.

Q. State your residence and occupation?

A. St. Louis is my residence, and I am a physician.

Q. How long have you resided in St. Louis?

A. All my life. I was born here.

Q. How long have you been practicing medicine?

A. I have been practicing medicine since 1874.

Q. Where were you educated in medicine?

A. In St. Louis, Berlin and Vienna.

Q. What schools in St. Louis?

A. The Medical Department of the Washington University.

Q. What schools in Berlin and Vienna?

A. The University of Berlin and the University of Vienna.

Q. You first graduated at the medical department of Washington University?

A. It was then the St. Louis Medical College.

12530 Q. And afterwards took the post graduate course in the Berlin and Vienna Colleges?

A. Yes sir.

Q. Or University?

A. Yes sir.

Q. What is the character of your practice?

A. I am devoting myself entirely to internal medicine.

Q. Do you treat typhoid cases?

A. Yes sir.

Q. How long have you treated typhoid cases?

A. From the first time I had the good fortune to have a patient with typhoid consult me.

Q. Are you connected with any of the hospitals in St. Louis?

A. Yes sir.

Q. What one?

A. St. Luke's Hospital, and I am consultant to the city hospital and I lecture to my classes in the city hospital once a week.

Q. What do you lecture on?

A. On medicine—clinical medicine.

Q. With reference to what character of diseases?

A. Internal medicine.

12531 Q. Is typhoid fever included?

A. Yes sir.

Q. In those lectures?

A. Yes sir.

Q. Are you acquainted with what is known as the Widal test?

A. Yes sir.

Q. How long has that test been used in St. Louis?

A. I should say about eight years. I may be wrong about that, but quite a number of years.

Q. You are acquainted with the disease known as typhoid fever?

A. Yes sir.

Q. Are you familiar with this Widal test for typhoid fever?

A. Yes sir.

Q. For what purpose is this test used, doctor?

A. To establish beyond a reasonable doubt the diagnosis of typhoid and to establish it as early as possible.

Q. What object is there in establishing this fact as early as possible?

A. The sooner you establish the diagnosis, the sooner will 12532 your treatment become an intelligent treatment.

Q. Doctor, state whether this test is used for determining the cause of the death or for the aid of the physician in making the early diagnosis?

A. It is used primarily in making the early diagnosis.

Q. And that is its principal object?

A. That is its principal object. When they die of the typhoid you do not ordinarily need the Widal to establish the cause of death.

Q. Is the disease of typhoid fever more easily treated and less likely to become fatal by reason of the fact that the physician learns early in the history of the case that it is true typhoid?

A. I think that is entirely probale, sir.

Q. Then, doctor, taking into consideration the value of the Widal test in making an early diagnosis of typhoid fever and also taking into consideration the fact that typhoid is a disease if properly treated in its early stages is less likely to become
fatal, what effect has the ability of the physicians to give
12533 their typhoid patients early treatment upon the mortality
record from typhoid?

A. I should think it would lessen it, lessen the mortality.

Q. Then the effect of the Widal test is to enable the physician to lessen the number of fatalities in their practice, so far as typhoid fever is concerned?

A. Yes sir, I think so.

Q. There would naturally be more deaths from typhoid when the Widal test was not employed than where it is properly employed?

A. I think that is entirely probable.

Q. Doctor, do infants and old people die of typhoid fever?

A. Yes sir, that does happen.

Q. Is it prevalent among infants and old people?

A. No.

Q. At these ages?

A. Not as compared to other ages?

Q. At what ages are persons most likely to have typhoid fever?

A. I should say between the ages of eighteen and forty or forty-five.

Q. Then persons between the ages of eighteen and forty-five are more susceptible?

12534 A. Yes sir.

Q. They are more susceptible to typhoid fever?

A. Yes sir, than infants.

Q. What season, doctor, is typhoid fever most prevalent in St. Louis? What season of the year?

A. I can not answer that because in my own practice I have had typhoid one year in the spring more prevalent than in the fall and then in the fall more prevalent than in the spring. I am not here in the summer time and do not know.

Q. You do not stay here in the summer time?

A. No sir.

Q. Then you do not know whether it is more frequent in the summer and fall than in the winter and spring?

A. No.

Q. State, doctor, if it is not a fact that you have observed more typhoid during the winter and spring months within the las few years than formerly?

A. Yes sir, I am very sure of that.

12535 Q. Doctor, state whether or not you know of any circulars ever having been sent out by the health department of the city of St. Louis to physicians practicing in St. Louis, urging them to make proper reports to the board of all typhoid fevers?

A. Circulars have been sent out by the board of health for the period of fifteen years at least, and perhaps longer, which make it obligatory upon the part of physicians to report a number of the infectious diseases, and among them typhoid, and add a punishment, a fine, I think, when the physicians neglect to respond to their questions.

Q. Why is it that physicians make these reports to the board of health and have so made them for the last fifteen or twenty years?

A. I think chiefly because it was demanded of them according to law.

Q. Because it is a matter of law?

A. Yes sir.

Q. And also a matter of city fines?

A. Yes sir.

Q. And has been?

A. Yes sir.

12536 Q. Did you receive a circular such as is just referred to about the time that the drainage canal was opened?

A. I do not recall it if I did. If all physicians received such a circular, I was probably not forgotten.

Q. You are acquainted with your profession in St. Louis?

A. Very well.

Q. You are in frequent communication with them and have been for years past?

A. Yes sir.

Q. State whether or not you ever heard members of your profession dicussing the reception of a circular about the time, from the city board of health, about the time of the opening of the drainage canal?

A. I do not recall that, do not recall that distinctly.

Q. Doctor, state what effect the fact that you have received these circulars from the board of health has had upon you in reporting cases and deaths in typhoid fever?

A. Personally?

Q. Yes sir?

A. None.

12537 Q. What in your opinion is the effect that it has had upon the physicians generally in the city?

A. I believe that many cases of deaths from typhoid have not been reported as typhoid for the reason that if the physicians had reported these deaths as typhoid the board of health would have at once demanded an explanation of them why they had not been reported as typhoid before the death of the patient.

Q. That is true and has been true so far as your judgment is concerned ever since circulars have been issued in St. Louis.

A. Yes sir, I believe that is true ever since.

Q. And is now true?

A. And is now true.

Q. Doctor, supposing that a physician certifies that one of his patients dies of congestive fever, what would yo understand by that term?

A. I should not know. I would fail to give an explanation.

Q. Would you consider the true cause of death to necessarily be typhoid fever?

A. If they pronounced it congestive?

Q. Yes sir?

12538 A. No.

Q. It might be something else besides typhoid?

A. Yes sir.

Q. Suppose a physician certifies that one of his patients dies of typho malaria, or remittent, or intermittent, or malaria, or bilious fever, or simple continued fever or any other of the nondescript fevers sometimes assigned by physicians as causing death, would you consider that such deaths so assigned were caused by typhoid fever?

A. It would depend a good deal upon the physician who returned the cause of death.

Q. When a death is reported as caused by a remittent or intermittent fever, it is not necessarily typhoid fever is it?

A. No sir.

Q. What else may it be?

A. Any of the diseases which have a fever as a symptom.

Q. Such as what?

12539 A. Oh, such as consumption.

Q. Ordinarily called tuberculosis?

A. Yes sir. That would perhaps explain it best for tuberculosis has fever—has a clinical symptom. You may have pneumonia with remittent fever.

Q. Or an intermittent fever?

A. Yes sir, that is possible. Any infectious disease that has fever as a symptom may have a remittent fever type. Meningitis is an infectious disease?

Q. Diphtheria?

A. Yes sir, that may have a remittent fever. It is more apt to be remittent than intermittent.

Q. Suppose the death be reported as being caused by typho-malaria, what would you say to that?

A. I should say that in my judgment there is no such thing as typho malaria. There may be a typhoid plus a malaria, and if he chooses to describe that as a typho malaria, that is his own
choice of nomenclature, but there is no specific organism
12540 to produce it. There must be two organsims, the typhoid
and the malaria organisms. Of course that is possible.

Q. Do infants and old people die of typhoid fever?

A. I think that is entirely possible, yes sir.

Q. Are they as likely to die as middle aged people?

A. If they get typhoid they are more likely.

Q. They are not as likely to get it?

A. They are not as likely to get it.

Q. What influence, if any, doctor, had the opening of the drainage canal on the 17th day of January, 1900, upon you in certifying deaths due to typhoid fever in St. Louis?

MR. TODD: Object to the question for the reason that there is no charge made by the defendant that the opening of the drainage canal has had any effect upon Dr. Fischel in making any incorrect diagnosis, and it is therefore not rebuttal, and that it is immaterial, incompetent and irrelevant.

Q. Question read.

A. I am quite sure that it made me extremely careful of my diagnosis, because naturally I felt that there was
12541 great danger of the sewage of Chicago contaminating our
water supply, and I wanted to make it at least clear to myself whether in my experience that danger existed, and therefore never reported a case as typhoid when the Widal was not positive. And if I may go on, I believe that before that time it was entirely possible that I reported cases typhoid that were not typhoid. Of one such case I have a very clear recollection, when I made the mistake in diagnosis, and the post mortem proved the fact that I was mistaken. I do not think that has happened to me since the opening of the Chicago canal.

Q. Doctor, what effect, in your opinion, has the opening of the drainage canal had upon your profession in St. Louis in the way of influencing it in the reporting of deaths from typhoid fever to the board of health?

MR. TODD: Object to the question on the ground it is incompetent, irrelevant and immaterial.

A. I think it made them more careful.

MR. JEFFRIES: Q. In what way, doctor?

A. In excluding the possibility of death from other
12542 diseases.

Q. In what way does the difference exist now, since the opening of the canal as compared prior thereto in the reporting of these deaths?

A. So far as I know in no way at all. We simply had to report the cause of death, if I understand your question.

Q. In other words, what was the difference in the precautions used in the reporting?

A. At present I report no death as due to typhoid in which the Widal agglutination test has not been found positive. Previous to the issuing of the circular and the penalty which it conveyed to physicians neglecting to report typhoid cases, the cause of death was frequently reported as typhoid when it might have been due to other diseases.

CROSS-EXAMINATION, by Mr. Todd.

Q. And the converse of the proposition is true, is it not, 12543 that many deaths from typhoid were reported as other diseases that should have been reported as typhoid prior to the opening of the drainage canal?

A. I think that is entirely possible. I think mistakes in diagnosis were made before we had the positive test for the given disease.

Q. Then if the typhoid conditions as to deaths in St. Louis prior to the opening of the drainage canal had been made with that same degree of care by the physicians that has been made since, there would have been a larger number of deaths reported than were reported to the health department?

A. I should be inclined to say no to that because after all the rule is that the clinical picture of typhoid is no clearer. We can make a positive diagnosis in the majority of cases without the Widal reaction, and I think therefore that typhoid is more readily recognized than many other diseases that in a way simulate it in a clinical course.

Q. How would you account, Doctor, for the number of deaths under the heading remittent, intermittent, typho-malaria, congestive and simple continued fever as evidenced by the board of health reports prior to January, 1900?

12544 A. That would be purely speculation if I answered that.

Q. Give me your best opinion as a physician in St. Louis?

A. I think many of these cases may have been tuberculosis. Tuberculosis is not always recognized,—the fever symptoms misleading one is accounted for otherwise. It is entirely possible that any one of the diseases which you have mentioned, and which after all mean only symptoms of fever, may have been tuberculosis. However, I know nothing about this—the answer to your question is merely speculative. I know nothing definite about that.

Q. Would not a good many typhoid deaths be classed under that heading?

A. Not now.

Q. Before?

A. Some, but you remember I told you before that typhoid runs a course that is so peculiar to typhoid that the diagnosis of the majority of cases is simple. Some were misdiagnosed and may have been tuberculosis.

12545 Q. It is simple to a physician skilled in diagnosis, but is it simple to the ordinary physician that is turned out from the medical schools during the last ten or fifteen years?

A. As simple as the diagnosis of any disease or as complicated as the diagnosis of any disease would be. It ought to be very simple. Whether it is or not, I do not know.

Q. Taking the number of intermittent and remittent and typho-malaria deaths that have appeared in the board of health reports in the city of St. Louis during the last six or eight years, would you say that those did not represent more typhoid than consumption?

A. I believe they represent more typhoid than consumption. Yes, sir, I think that would represent more typhoid than tuberculosis.

Q. The number of deaths as represented by typhoid would be a very small percentage of those prior to 1900 that would not be typhoid in your opinion, would it not?

12546 A. Yes, I think that is probably correct.

Q. Now, if the circular after the opening of the drainage canal should have an effect upon you, a doctor of recognized standing, in the profession, to be more careful in your diagnosis of typhoid, would it not have an equal effect upon doctors less qualified and competent than yourself, in reporting typhoid cases?

A. I think on the whole it has made the physicians of this city more careful in reporting the typhoid cases.

Q. And if the board of health report should disclose that the number of typhoid fever deaths have increased since the opening of the drainage canal, and the number of intermittent, remittent, typho-malaria, congestive and simple continued fever deaths have decreased since the opening of the canal, that would evidence the effect of that letter after the opening of the canal upon the physicians of the city in making more careful diagnosis not only of typhoid fever, but of other diseases, would it not?

A. It certainly would of typhoid fever and I think of

12547 other diseases. I think physicians are more careful than they have been.

Q. And if that effect is manifest since the opening of the canal in more careful diagnosis of typhoid fever and other diseases, it shows that the physicians prior to the opening of the drainage canal were not as careful in their diagnosis as they should have been?

A. I think in regard to typhoid fever the chief reason for their having become more careful was the penalty attached by the board of health in case physicians did not report typhoid fever.

Q. Do you know of any case of a physician within the last ten years that has been prosecuted, convicted and fined for not reporting typhoid fever?

A. I know of one who has been called to account and that is myself when I did not report a case of typhoid fever because there was absolutely no evidence that satisfied me that the case was typhoid until perhaps three days before the patient's death when the Widal reaction became positive. I was then
12548 summoned before the board of health to give my reasons for not having reported that case as typhoid before. I was not fined for I think my explanation was satisfactory.

Q. Do you know of any other times?

A. I do not know of any other.

Q. Do you know of any case prior to the opening of the drainage canal in January, 1900, where the board of health invoked the ordinances in compelling doctors to report cases of typhoid fever?

A. I do not know from my own knowledge.

Q. Doctor, is it not a fact that the fatality of typhoid fever cases is mitigated largely by the ability of the physicians who attend the cases?

A. That is a mooted question, sir. I should not feel competent to determine that.

Q. What I mean is if you have a competent first-class physician treating a typhoid case, is not that case more likely to recover than if it is in the hands of a less skilled physician?

A. I should say yes.

12549 Q. And the number of deaths from typhoid fever may decrease or increase in a given community, depending upon the skill of the physicians that are handling those cases, other things being equal?

A. Yes sir.

Q. It is necessary for any intelligent physician to know what his patient is suffering from in order to treat him intelligently?

A. Yes sir.

Q. That is the aim of the advanced schools in medicine, to simply diagnose so that the doctors with less opportunity can avail themselves of that broader experience?

A. Yes sir.

Q. And the Widal test is one of the tests that doctors employ for the proper diagnosis of typhoid fever?

A. As early as possible, yes sir.

Q. As early as possible?

A. Yes sir.

Q. There are other symptoms of typhoid fever that a 12550 skilled physician would act upon, even though he did not receive the Widal reaction in the treatment of a typhoid case, would he not?

A. I do not believe that any physician now would be willing to accept the diagnosis of typhoid without having obtained the positive Widal reaction. I should have in mind everything else.

Q. But would your treatment be radically different as long as you had the symptoms to direct you towards the condition of typhoid?

A. I should say no.

Q. Buf you recognize the fact that in other physicians, young men that have limited educational experience, that have gone through medical colleges and just simply been turned out as a great many of them are turned out, would not have the experience in interpreting symptoms that an old practitioner would?

12551 A. Certainly that is true.

Q. And in cases of that kind the patient is the one that suffers?

A. He might suffer; yes sir.

Q. To what would you attribute the number of deaths reported in the board of health reports of the city of St. Louis under the heading intermittent, remittent, typho-malaria, congestive and simple continued fevers, to a faulty diagnosis?

A. In many of these cases certainly, yes sir.

Q. And do you recognize intermittent, remittent, typho-malaria, congestive and simple continued fevers as distinct types of disease?

A. No.

Q. They are terms that have grown up in the profession and are employed today by doctors who are not up with the progress of the medical profession?

A. I think that must be true.

Q. Is not that true?

A. I believe that is true.

Q. And when you find a number of deaths aggregating in the neighborhood of 200 in a city the size of St. Louis, 12552 reported under the heading of intermittent, remittent, typho-malaria and congestive fevers, does not that lead you to the conclusion that there is a great number of doctors in the city of St. Louis, the same as in any other city that are not abreast to the profession?

A. Certainly.

W. E. FISCHEL.

ADJOURNED until 2:15 p. m., same day, May 23, 1904.

12553 2:15 p. m., Monday, May 23, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

DR. LUDWIG BREMER

a witness called on behalf of the complainant, being duly sworn by the Commissioner, was examined in chief by Mr. Jeffries, and testified as follows:

Q. State your name?

A. Ludwig Bremer.

Q. State your residence and profession?

A. 3723 West Pine Street, St. Louis; physician.

Q. How long have you been a practicing physician?

A. About thirty-four years.

Q. When did you graduate and where?

A. I graduated in 1870.

Q. From what school?

A. The St. Louis Medical College, now the Washington University.

Q. Were you then or afterwards connected with the city hospital of St. Louis?

12554 A. Yes sir, I was interne at the city hospital.

Q. Were you in any way connected with the quarantine?

A. Yes sir, I was resident physician of that hospital which was a part of the city hospital. It was then a general hospital which received the superabundant patients of the city hospital. It was not the small pox hospital as it is now.

Q. What was the length of time you were connected with the city hospital?

A. I was there about a year.

Q. Doctor, state whether or not you have ever practiced medicine in the country?

A. Yes sir, I practiced about nine or ten years, general practice in the country, that is, in a small town, Belleville, Illinois.

Q. Have you ever studied abroad?

A. Yes sir.

Q. Where?

A. I studied at Strasburg and Zurich, Switzerland, and Paris.

Q. What subjects did you study there?

A. Internal medicine and pathology.

Q. State whether or not you studied at Berlin?

12555 A. Yes sir.

Q. At Vienna?

A. No sir. I was in Berlin, and in Vienna later on.

Q. Have you ever taught in any medical school?

A. Yes sir.

Q. What subject, Doctor?

A. Histology, pathologic anatomy; microscopy; biology and nervous diseases.

Q. State whether or not you have lectured at the city hospital?

A. Yes sir, I did.

Q. Have you ever made any discoveries, Doctor, with reference to the blood tests for any particular disease or germ?

A. Yes sir, I am credited with the discovery of the blood test for diabetes.

Q. Have you ever written or published any scientific medical articles?

A. Yes sir, a good many.

12556 Q. In your general practice, Doctor, have you treated typhoid fever patients?

A. Yes sir.

Q. State whether or not you have been called in consultation with other physicians in the treatment of this particular disease?

A. Yes sir, I have been called into consultation to make the diagnosis in cases that were suspected of typhoid, especially in the ante Widal days.

Q. Are you acquainted with the Widal test, Doctor?

A. I am acquainted with it, yes sir.

Q. Have you used it?

A. I have used it, I should say not particularly in my own practice, but in order to verify its scientific significance, quite a number of times, a number of years ago.

Q. What in your judgment, Doctor, has been the effect of the use of the Widal test upon the relative number of deaths in typhoid fever in St. Louis since its use as compared to the same period of time prior to the use of the test by the physicians?

A. I do not know of any effect.

12557 Q. What is the purpose of the Widal test?

A. To make an early diagnosis.

Q. What particular advantage in the treatment of the disease of typhoid is obtained by being able to make this early diagnosis?

A. I don't understand.

Q. What particular advantage is there in reference to the treatment of this particular disease in making an early diagnosis and ascertaining at an early stage of the case that it is true typhoid?

A. Well, I should think the earlier one knows that, that has to deal with the case of typhoid, the sooner proper measures were resorted to and the more powerful drugs such as quinine and so on will be avoided.

Q. And therefore the mortality from typhoid will be reduced?

A. Well, I do not know that it would be reduced, but the patient is placed under more favorable conditions for recovery.

Q. Are you acquainted with the medical fraternity in St. Louis, in the profession, in general?

12558 A. I know a good many doctors.

Q. Frequently called in consultation by them?

A. Rather so.

Q. And have been for years past?

A. Yes sir, for a number of years.

Q. Do you attend any medical associations in St. Louis now?

A. Yes sir.

Q. Meetings and conventions?

A. Yes sir, I attend the St. Louis Medical Society, for instance.

Q. Have you been an officer of that Association?

A. Yes sir, I was president.

Q. In those meetings do the physicians of the city discuss the various diseases that they have in their practice?

Mr. Todd: I object to the question as incompetent, irrelevant and immaterial and not proper rebuttal.

A. Are such diseases discussed?

Mr. Jeffries: Q. Yes sir?

A. Why certainly; yes sir.

Q. With reference to typhoid and other infectious disease, is the prevalency of those diseases discussed by the medi-

12559 cal fraternity of St. Louis at these meetings?

Mr. Todd: Objected to for the same reasons.

A. Well, I do not remember that any paper has been read or a formal discussion has been had, but physicians talking socially.

Mr. Jeffries: Q. They talk promiscuously about conditions?

A. Yes sir.

Q. I will ask you to state, Doctor, whether or not since January, 1900, there has been an increase in the death rate from typhoid fever in St. Louis, as you gather it from this professional talk among the members of your fraternity in St. Louis?

Mr. Todd: Object to the question for the reason that it is not proper rebuttal, and for the reason that complainant has gone into the typhoid condition in St. Louis on direct examination, and for the further reason that whatever was said at an informal discussion at a Medical Society is not competent evidence, but purely hearsay, and for the further reason that the question is incompetent, irrelevant and immaterial.

Q. Question read.

A. I gathered from the talk with the physicians and from 12560 hearing my patients talk about it and the cases occurring in their family. I could not state that there has been an increase positively, but that is my impression, that there has been an increase. This is my impression that there has been.

Mr. Todd: I move to strike out the answer for the same reasons given in my objection to the question.

Mr. Jeffries: Q. Now, upon what do you base your impression, Doctor?

Mr. Todd: Object to the question for the reason that the impression of this witness is not competent evidence, and for the further reason it is not rebuttal and therefore is incompetent, irrelevant and immaterial.

Q. Question read.

A. I base my impression upon conversation with physicians and conversation with the relatives of the sick of typhoid fever patients and conversations with druggists.

Mr. Todd: I move to strike out the answer for the same reasons that are assigned as an objection to the question.

Mr. Jeffries: Q. Based upon these conversations which 12561 you have held with the members of your profession, and from what you have learned from them at the various meetings which they held in St. Louis, and upon the conversations that you have had with the druggists and all other persons coming in contact with you as a physician, state, Doctor, what your opinion is with reference to the question as to whether there is or has been an increase in the rate of typhoid death mortality in St. Louis since January, 1900?

Mr. Todd: Object to the question for the reason that it is incompetent, based upon hearsay; for the further reason that complainant went into the question of increase of typhoid fever in the city of St. Louis, in chief, and therefore is not competent in rebuttal, and for the further reason it is incompetent, irrelevant and immaterial.

Q. Question read.

A. I think it is the general consensus of opinion that there has been a gradual increase in the number of cases of deaths from typhoid fever since the opening of the canal.

Mr. Todd: I move to strike out the answer for the reasons given in my objection to the question.

12562 Mr. Jeffries: Q. That is your opinion is it Doctor?

A. It is my opinion, yes sir.

Mr. Todd: I object to the question for the same reason and move to strike out the answer for the same reasons.

CROSS-EXAMINATION

By Mr. Todd:

Q. Doctor, do you know how many cases of typhoid fever were in the city of St. Louis prior to the opening of the drainage canal for a period of four years?

A. I do not.

Q. Do you know how many cases of typhoid fever were in the city of St. Louis during the last four years?

A. I do not.

Q. Have you made any comparison of the typhoid fever statistics of the city health department of the city of St. Louis for the last eight years?

A. No sir.

Q. Is typhoid fever in St. Louis generally distributed in 12563 all localities alike?

A. Not always.

Q. That may appear in some localities more frequent and be absent in others may it not?

A. Yes sir, comparatively absent.

Q. Typhoid fever may be due to local causes may it not?

A. So it would seem.

Q. Is your practice general throughout the entire city or confined to special localities?

A. Throughout the city.

Q. Have you ever taken up this question of typhoid fever in any of your meetings and discussed it with a view of ascertaining whether it is on the increase or decrease?

A. I don't remember that.

Q. That has never been made a subject of discussion at any one of the meetings that you have attended at the associations has it?

A. Not of those that I have attended.

12564 Q. In figuring out the question of increase of typhoid fever based upon your impressions, did you take into consideration the increase in population during the last four years, due to the influx of people here attending the Louisiana Purchase Exposition?

A. I did not take that into consideration.

Q. Would not that be an element to figure out, whether there is an increase or decrease?

A. It might be included as a factor, I think.

Q. Have you observed whether or not, since the Spanish-American war there has been a general increase in typhoid fever throughout the country on account of the returning soldiers from the fever camps at Chickamauga, Tampa, Florida and Mountain Point, etc.?

A. Well, I have read of very severe epidemics, but what part the soldiers play I do not know.

Q. I am not speaking of epidemics. I am speaking of a general rise in typhoid fever throughout the country.

A. I am not aware of it, not personally, not from my reading.

12565 Q. In the diagnosis of typhoid fever do you use the Widal test in all cases that you treat?

A. I never employ the Widal test myself, now. I used it simply for scientific research to find whether there was something in it, when it was new.

Q. Is it a test that is universally adopted by the physicians of St. Louis in the diagnosis of typhoid fever, as far as you know?

A. Yes sir, universally. Well, there may be exceptions.

Q. Why did you abandon it, Doctor?

A. I was at the time very intensely engaged in microscopy and in pathological anatomy and made original investigations. For that reason, when this test was first published, I tried to verify it. Since then I have never had an opportunity or have never had an occasion to use it because there are so many people to do that. At the board of health it is done, and I would not take time for that.

Q. Do the doctors perform this test themselves or turn it over to the board of health of the city of St. Louis to do it for them?

A. There are a number of gentlemen here who have private
12566 laboratories that do it, but I suppose the greater number
of the tests are made at the bacteriological institute, the City Institution.

Q. Do all the older practitioners in the city of St. Louis who are not connected with medical colleges rely upon the Widal test?

A. I do not know.

Q. In the diagnosis of fevers, is it not a fact that the doctors with a few exceptions fail to resort to the Widal test?

A. Is it not a fact that they fail to resort to the Widal test in the diagnosis?

Q. Yes sir, the typhoid fevers?

A. Well, I am not sufficiently familiar with the ways of the general practitioner, and therefore I could not answer that question.

Q. How many doctors have you in St. Louis?

A. It is variously estimated from twelve to fifteen or sixteen hundred.

Q. Among those twelve or fifteen hundred doctors a great

12567 proportion of them are young doctors that have been turned out of the medical schools in the last three or four years, are they not?

A. I do not know the proportion, but I should think there were quite a number, but how many there are I do not know.

Q. In the diagnosis of typhoid fever it requires a skilled physician to make an accurate diagnosis in most cases does it not?

A. I do not know, a general country practitioner that has not had much medical training can make out a case of typhoid fever after the second week, even if that man has not had much medical training. You mean is it very difficult? Well, I say it is not, from the general appearances and the symptoms of the disease; but that is my private opinion.

Q. Doctor, in the diagnosis of malarial fever, does it require a skilled physician to make that diagnosis?

A. Of malarial fever you ordinarily could make a diagnosis easily if it is not complicated. The typical case it certainly does not require a skilled physician.

Q. Do you recognize such fevers as are characterized by
12568 the names intermittent, remittent, typho-malaria, congestive and simple continued fevers as distinct types of disease?

A. They used to be. They are not now.

Q. Are they right now or were they right formerly?

A. Well, what is right and what is wrong, we don't know. Just at the present time such cases as remittent and intermittent and congestive fevers are not recognized any more in the classification, that is in the scientific classification.

Q. Those fevers which are called by doctors as remittent, intermittent, typho-malaria, congestive and simple continued fevers, if diagnosticated according to modern conditions and advanced medical learning would be classified either as malaria or typhoid fever would they not, in the majority of cases?

A. I would not say that with such a precision. I would say that, no doubt, a number of these cases have been typhoid, being entirely unrecognized cases or mistaken cases of ty-
12569 phoid. I do not know what percentage.

Q. So that it is only in exceptional cases that it requires great medical skill to properly diagnose malarial fever?

A. Yes sir.

Q. And that is true of typhoid?

A. True of typhoid, yes sir.

Q. In the absence of the Widal test, what are the symptoms of typhoid fever that are generally recognized?

A. There is the fever curve. Then there is the peculiar drowsiness, and pain on pressure on points in the abdomen, and the eruptions peculiar to typhoid and what is generally called the habitus of the patient, that is, as the impression one gathers from looking at the patient and by the peculiar nature of the feces.

Q. May not a patient have all the symptoms that you have indicated and yet not give the Widal reaction, and still have typhoid fever, all or any one that you mention?

A. May all these symptoms be present by that you mean in combination or single?

Q. Present in patient?

12570 A. And not be typhoid?

Q. And yet not get the Widal reaction?

A. Well, although these symptoms may be present the reaction may be wanting; I mean the positive reaction.

Q. Would the fact that the disease of typhoid fever, if properly diagnosed immediately after the patients contracted the disease reduce the mortality of the typhoid patients?

A. Well, this is a hypothetical question which I do not think I am able to answer.

Q. Is there any specific for typhoid fever in medicine?

A. No sir.

Q. The same as quinine is in malaria?

A. Not that I know of.

Q. In the treatment of typhoid fever patients, it is as much in the nursing and care as it is in the medicine, is it not Doctor?

A. Principally in the nursing.

Q. The cure does not depend upon the medicine that is given does it in a majority of cases?

A. Some doctors are strong believers in medicine. I do not
12571 personally believe much in medicine.

Q. It is a generally recognized fact is it not, that the best treatment for typhoid fever patients is good nursing and little medicine?

A. That is the trend of the present state of medicine.

Q. So that the advantage in making a proper diagnosis of a patient is to prevent the treatment of that patient for some disease that requires medicine which would be to the detriment of the patient if it was given?

A. Yes sir.

RE-DIRECT-EXAMINATION

By Mr. Jeffries:

Q. Doctor, do you remember the slight epidemic of typhoid fever in St. Louis in November and December, 1899?

Mr. Todd: I object to the question on the ground that that has already been testified to by Dr. Ravold and Dr. Teichmann in the original case, and not proper rebuttal, and therefore incompetent, irrelevant and immaterial.

12572 A. I remember it very well.

Mr. Jeffries: Q. State whether or not that epidemic, Doctor, was confined to any particular part of the city?

A. It seemed to be confined to the part of the city where I live, out in the west end. I do not know the number of the districts, it is along West Pine and on Lindell Boulevard, and in that region towards Forest Park.

Q. Doctor, do you know anything about the history of the use of private filters in the city of St. Louis?

Mr. Todd: Object to the question as incompetent, irrelevant and immaterial, and not proper rebuttal.

A. Well, the use of the private filters has increased very materially, on the advice of the physicians.

Mr. Jeffries: Q. Since when?

A. During the last six or seven or eight years. I do not know whether they are still on the increase, but I know that a year or two ago I heard it from the physicians generally they recommended filtered water and boiling the filtered water afterwards.

Q. State in a general way, Doctor, the changes in the

12573 recommendation and the changes in the water that have been brought about by the recommendation of the physicians in St. Louis during your practice here?

Mr. Todd: I object to the question as not rebuttal and therefore incompetent, irrelevant and immaterial.

A. When the fact became generally known among the profession that typhoid fever was principally a water born disease the physicians recommended the boiling of the water and in this city the filtering of water, in order to get rid, presumably, of the germs. There were a good many articles published a number of years ago by the Sunday papers recommending the boiling of water, and I remember that there was quite a crusade against unfiltered water and the physicians were interviewed in regard to the importance of filtering and boiling afterwards, and I know that since in all well regulated households in this city it has been the custom, and I think the invariable custom, 12574 to drink nothing but filtered and boiled water, filtered first and boiled afterwards, and when a case of typhoid arises the question is always asked, did you boil your drinking water, or did you go anywhere where you could get or drink water that was not filtered. I believe that at the present time among educated people, and with even a number of the people of the lower walks of life, that now they know that they have to boil the water in order to protect themselves from causative agents of typhoid fever. I think that idea is pretty generally spread among the population.

Mr. Todd: I move to strike out the answer for the same reasons as stated in my objection to the question.

Mr. Jeffries: Q. State, Doctor, whether or not this education on the part of the people with reference to filtered and boiled water has not been increased and extended considerably within the last three or four or five years?

A. I think it is. I do not know whether it has increased in the three or four last years, but I know this that every physician of common sense, the family physician, recommends 12575 the boiling and filtering.

Q. Today?

A. Today. That is one of the maxims of the medical profession now, and especially since preventitive medicine is given the first place in the practice of medicine. Of late years every doctor is more or less of a hygienist, which they did not use to be in former times, while now, by the teaching of bacteriology in the colleges, hygiene is very much promulgated; and one of the very first things in the practice of medicine is the prevention of infectious diseases, especially in the case of typhoid is this progess that we are talking of.

Q. And this recommendation from a hygienic standpoint on the part of the physicians of St. Louis is one of gradual growth is it not?

A. I think it is.

RE-CROSS-EXAMINATION,

By Mr. Todd:

Q. Are you acquainted with the epidemic of 1892?

A. Yes sir.

12576 Q. That epidemic afforded a stimulus to the physicians to advise the boiling of the water of the Mississippi River did it not?

A. It afforded a stimulus to me.

Q. Did it not afford it to any well informed doctor?

A. Well, I believe it did. To what extent, I do not know, but then there was a crusade in about 1896 or 1897 when bacteriology was a much more recognized branch of medicine than it was at that time; since it was recognized even by the daily press, the papers took it up and that matter became public property.

Q. From 1896 to 1900 the medical fraternity of St. Louis recognized the fact it was unsafe to drink the water in its raw state as supplied to the citizens?

A. There were a good many that did not recognize it, for they looked upon bacteriology as a snare and a delusion.

Q. There are some today that hold to that view?

A. Very few.

Q. There are some?

A. Yes sir.

12577 Q. They still stick to that?

A. Yes sir. I do not know any at the present time but I did in former years.

Q. From 1896 to 1900 it was generally recognized that the water supply of the city of St. Louis was an unsafe water for drinking purposes in its raw state?

A. I should think it was about that time that the suggestion began and since then it has been kept up.

Q. In other words the medical association of St. Louis has kept abreast of the bacteriological researches and the sanitary problems have also advanced on the line of getting a safe, pure drinking water for domestic uses?

A. The medical profession has been gradually improving and with the younger element coming in, the bacteriological truths, or so called truths, have been more and more recognized.

Q. Is it not a fact that the doctors and citizens of St. Louis, since 1865, have recognized the fact that the water supply of St. Louis required filtering?

Mr. Jeffries: Objected to as immaterial.

A. No sir.

Mr. Todd: Q. Do you know that the city council of the city of St. Louis sent a man to Europe, by the name of Kirk-
12578 wood, to investigate the filtration plants of Europe, and
that he came back and published the results of his investigations in the most elaborate work on the subject that is extant today and is recognized by all authors on filtration?

Mr. Jeffries: Object to the question for the reason that it is incompetent in this connection, the city of St. Louis, the City Council and people residing therein not having accepted this report made by this gentleman mentioned in the question, the recommendations of the report, and not having acted upon them.

A. I must plead my ignorance, in regard to the sending of this expert to Europe, but I know in regard to the infection of the water, in the cases that I have read, that not many years ago, and I do not know at present whether there are any such—there were many parties in St. Louis that said that the unfiltered water of the river was healthy and they would not drink it in any other form because the filtered water to them tasted stale and
they wanted it in the natural state, and that has been the
12579 case. I do not know whether they are still in existence,
but five or six years ago there were certainly a good many. Whether there are any now or not I do not know. There

were a good many physicians who didn't believe at all in the filtering of water, but that is a gradual process and now it has reached probably to the climax that everyone believes in filtering and boiling, principally boiling.

Mr. Todd: Q. The medical fraternity of the city of St. Louis recognized the necessity for filtering and boiling the water before 1900, did they not?

A. Oh, yes. Then the sentiment was growing and the education was going in that direction, but that was certaintly not a sudden process. I think it took years to accomplish that in the case of the general public. The public was very conservative.

Q. It took years to stop physicians from bleeding patients?

A. Yes sir.

Q. The water supply of St. Louis has always been turbid has it not?

Mr. Jeffries: Object to the question for the reason it is not competent cross examination.

12580 A. As long as I remember it has been turbid, that is since 1866, but it used to be of a different color. It used to have a sandy complexion, and now it has an inky one. It used to look sandy. That was the Missouri river water, and that had a different taste in the late 60's—it was only water—but then the sewage of the city, from Mill Creek, a little rivulet in the northern part of the city, that polluted the city water, and then came epidemics, and people were afraid to drink it, and it lost its good taste. It lost its good looks too.

L. BREMER.

12581 DR. ALBERT E. TAUSSIG,

a witness called on behalf of the complainant, being duly sworn by the Commissioner, was examined in chief by Mr. Jeffries, and testified as follows:

Q. State your name?

A. Albert E. Taussig.

Q. How long have you lived in St. Louis?

A. All my life.

Q. How long have you been practicing medicine?

A. I have been practicing medicine at my present location for eight years, but I had service in the City hospital previous to that.

Q. How long had you been at the city hospital?

A. One year.

Q. Now, what is your office number?

A. 2647 Washington Avenue.

Q. Where did you receive your education, Doctor?

A. I graduated from the Smith Academy, a branch of the Washington University, in St. Louis, and took the degree of Bachelor of Arts at Harvard University, and then I took
12582 the degree of M. D. at the medical department of the Washington University and served a year as interne at the city hospital, and a year and a half in the University of Berlin, taking both clinical and laboratory work.

Q. That was at Berlin, Germany?

A. Yes sir.

Q. What was the character of your work at the city hospital?

A. I was an interne, served in all the various divisions of the hospital and took everything that came.

Q. State whether or not typhoid fever cases came under your observation at the hospital?

A. Yes sir.

Q. Doctor, what connections have you now in a professional way with any medical college or institution?

A. I am lecturer in medicine and Senior Instructor in clinical chemistry and microscopy in the medical department of the Washington University, and chief of one of the two medical clinics in the same University, and I am on the staff of St. Luke's Hospital.

12583 Q. State whether or not in your general practice in St. Louis that you have been called upon to treat typhoid fever?

A. Yes sir, I have.

Q. Do you have any specialty in your practice?

A. Internal medicine.

Q. And in that is included typhoid fever?

A. Yes sir.

Q. Are you acquainted with the typhoid epidemic that occurred in St. Louis in November and December, 1899?

Mr. Todd: Object to that question on the ground that it is incompetent, irrelevant and immaterial, and not proper rebuttal.

A. I had a number of cases at that time.

Mr. Jeffries: Q. Can you state whether or not this epidemic was general over the city or whether it was localized in a community?

A. It was rather sharply localized, I think in about the central part of what is called the west end.

Q. It was not general over the city?

A. Not general over the city.

12584 Q. Doctor, do you know whether or not the use of private filters in the houses and the process of boiling water for drinking purposes is in vogue in St. Louis or not?

Mr. Todd: Objected to as incompetent, irrelevant and immaterial and not proper rebuttal.

A. Yes sir, both boiling and filters are used a good deal, considerably more, in my opinion, than they were in past years. The use of both of boiling for sterilizing water and filters is steadily on the increase. These families whose regular physician I am, all boil their water. I insist on that and most of them filter their water.

Mr. Jeffries: Q. State whether or not the recommendations which you give in this respect are those that are generally given by the practitioners in your profession in St. Louis?

Mr. Todd: Object to the question for the reason it is incompetent, irrelevant and immaterial and not proper rebuttal.

A. Yes sir, I think practically all physicians advocate that very strongly.

12585 Mr. Todd: I move to strike out the answer for the reasons given in my objection to the question.

Mr. Jeffries: Q. You are acquainted with the advice and recommendations that the profession give to their patients in the city?

Mr. Todd: Object to the question as hearsay and not competent.

A. Those matters are discussed when physicians meet socially and we know pretty well what the others are doing.

Mr. Todd: Move to strike it out for the reasons stated in the objection.

Mr. Jeffries: Q. And from these discussions which you have in the medical associations, etc., what are your observations with reference to the use of private filters and boiling water for drinking purposes?

Mr. Todd: Objected to for the same reasons as heretofore stated.

12586 A. Both boiling and the use of filters are becoming more and more universal.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. State whether or not from the observations and the recommendations which you personally give that these precautions are always observed by the citizens?

Mr. Todd: Object to the question for the same reason.

A. They are not always observed, of course, but one tries to have them observed as well as possible. There are always some people that are careless and others that are careful.

Mr. Jeffries: Q. Are you acquainted with the general use of private filters in St. Louis, about the time that you commenced to practice, as to the number?

A. Not at all; only in a general way. We get a general sort of an impression. I do not know the statistics.

12587 Q. State whether or not you have observed the use of private filters in the private houses in St. Louis have increased during the last four years over conditions existing prior thereto?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. While I have not the statistics, my impression is that they have increased.

Mr. Jeffries: Q. Upon what do you base this impression or opinion?

Mr. Todd: Objected to for the same reason.

A. Simply that a greater number of families about whom I know something have put in filters.

Mr. Todd: I move to strike out the answer for the same reason as stated in my objection to the question.

Mr. Jeffries: Q. Doctor, you received circulars from the city board of health admonishing you to report promptly all deaths from typhoid and other infectious diseases, what effect, if any, did such circulars have upon you in making these reports, deaths or cases?

A. They might make me a little more observant of my
12588 duties where otherwise, if I had a case of typhoid fever I
might neglect to report it as such and the effect would be doubtless, that I should report a greater number of cases of typhoid fever. I do not think it could possibly have any influence on the death certificates that I should write, for that depends upon my own diagnosis. I have to report those. If it had any influence, though I do not think I should yield to the temptation, it might tempt me not to report a case that I had lost as typhoid, if I had neglected to report it as typhoid before death. Do you care for any instance of that kind?

Q. You might, if you care?

A. I had one case of typhoid fever some years ago, in which I did not make the diagnosis until the patient was moribund, so that I had not reported it as a case of typhoid fever. When the patient was dead I put typhoid fever on the death certificate. The next day I got a very sharp note from the health commissioner calling attention to my neglect in not having reported the case before and threatening me with punishment unless I could make a satisfactory explanation.

Q. How many years has it been since this particular in-
12589 stance that you have reference to occurred?

A. Perhaps four or five years or something like that.

CROSS-EXAMINATION

By Mr. Todd:

Q. How long has the necessity for the boiling and filtering of the water in the city of St. Louis, in your opinion, Doctor, existed?

A. I think it always has been a wise precaution to boil the water, or at least since it seemed probable that typhoid was a water born disease.

Q. How long has it been since it has been known that typhoid fever was a water born disease?

A. I do not know. It was a knowledge that has come rather gradually and only gradually spread through the profession.

Q. It has covered a period of over ten years?

A. I am not certain about the dates.

12590 Q. So then the condition that obtained in the city of St. Louis during the last ten years was such as to require the water to be boiled and filtered to prevent typhoid infection?

Mr. Jeffries: Objected to as immaterial.

A. During at least that time it has been a wise precaution.

Mr. Todd: Q. That precaution was emphasized by the epidemic in 1892 when the intake tower was situated at Bissel's Point, and the great epidemic broke out in the city which was directly traceable to the water supply at Bissell's Point?

A. Yes sir, that caused a great many people to begin the systematic boiling of water who had not done so before.

Q. Now, in the letter sent out by the Board of Health in 1900, to the physicians, calling attention to reporting typhoid fever, did not that letter have an influence to stimulate the doctors to more careful diagnosis of typhoid fever?

Mr. Jeffries: Objected to, for it assumes that such a letter was sent out, and the question is not proper.

A. I do not remember very distinctly about such a letter.

12591 I should think that such a letter, if received, might have made a person more careful.

Q. Assume that the chemist to the board of health, Dr. Teichmann, testified in this case that such a letter was sent out to all the doctors, would such a letter stimulate the doctors in St. Louis to a more careful diagnosis of typhoid fever?

A. Those that needed such a stimulus probably might be stimulated. The man that had been in the habit of being careful and conscientious in diagnosing all his cases of typhoid would not be affected. It would certainly have the effect of causing a greater proportion of all cases to be reported, and as I understand it that was the object of the letter, whether it would have any influence on the diagnosis is a very different question.

Q. You understand, Dcotor, that laws are not passed for the purpose of reaching the people that naturally observe the laws, but for those that have a tendency to break them?

Mr. Jeffries: Objected to as incompetent, irrelevant and immaterial.

Mr. Todd: And the same is true of doctors?

12592 Mr. Jeffries: Objected to for the same reasons.

A. Yes sir, I supose that is true. I do not know.

Mr. Jeffries: Object to the question and move to strike it out and also strike the answer out for the reason it is putting a legal proposition to the witness, when he is not a lawyer and therefore not supposed to know.

Mr. Todd: Q. You do not regard doctors as a class different from any other profession as a class, do you, as far as the conscientiousness in the performance of duties is concerned?

A. Yes sir, I think on a whole they are apt to be a little more conscientious.

Q. Do you really think that?

A. Well, there is a certain amount of self sacrifice that is unavoidable in the practice of medicine and I think a man gets to be pretty conscientious on the average. There are some black sheep.

Q. A letter of that kind sent out to doctors who are careless in reporting typhoid deaths would have a stimulus with them in making them more careful in reporting typhoid fevers, would it not?

12593 A. Would make them more careful in reporting typhoid deaths?

Q. Deaths, I mean.

A. The assumption you made, as I understood it, referred to the reporting of typhoid cases.

Q. I am dealing entirely in deaths. If anything is said to the contrary before on the statement, I mean deaths.

A. Do I understand you to say that if a circular had been sent out asking them to be more careful in reporting typhoid deaths, that would have had an effect on the physicians?

Q. Yes sir, in making more careful diagnosis?

A. I do not think that any one could have the nerve to send out a circular asking the physicians to be more careful in reporting the typhoid deaths. He can not unless he makes a diagnosis. Generally, if the patient is dead, he can not make any further diagnosis. Such a letter could only affect the reporting of cases before death. When the patient is dead, that case is closed unless there is a post mortem.

Q. But if a patient who is being treated by a physician for a disease which the physician has wrongfully diagnosed
12594 as typhoid fever or some other disease, if the patient
dies, then his report, whatever they have diagnosticated the case to be, is that not in the absence of post mortem examination?

A. If they are perfectly honest about it, otherwise, as I have stated, if they had a case that at the last moment they recognized as typhoid, and if they had received a letter threatening penalties for failure to report such cases they might be very strongly tempted to report the case as something else on the death certificate.

Q. The diagnosis of typhoid fever, does that require any skill?

A. In a certain proportion of cases it does.

Q. If it should appear in the board of health statistics of the city of St. Louis—

A. May I ask—you said in the diagnosis of typhoid cases?

Q. Cases, typhoid fever cases?

A. Yes sir.

Q. If it should appear in the board of health reports of the city of St. Louis that there were only about 200 cases reported under the head of remittent, intermittent, typho-malaria and congestive fever and simple continued fevers, and it was
12595 not recognized by the advanced physicians in medicine
that these diseases so named are distinct types of disease, to what would you attribute the deaths so recorded?

A. I do not think that any man can possibly tell, assuming to a certain extent that is probably true that a large proportion or a certain proportion of these cases are so diagnosed because the physician in charge does not know what he is about, then I do not think anybody can say what they were. Some were typhoid and some consumption and some probably still other diseases, but I could not say what they were.

Q. If such a proportion of deaths should be wrongfully diagnosed, as intermittent, remittent, typho-malaria, congestive and simple continued fevers, as is evidenced from the board of health reports, would not such a diagnosis reflect upon the ability of the physician sending in such causes of deaths from diseases which could be properly diagnosed, if they had sufficient skill to do it?

A. Assuming that these are not proper causes of death—some of them are.

Q. Assuming that they are not?

A. Why certainly.

12596 Q. Do you recognize intermittent fever as a distinct type of disease?

A. Intermittent fever is rather the name of a symptom than of a disease in itself, a symptom which can characterize a number of different diseases.

Q. Do you recognize remittent fever as a distinct type of disease?

A. The same holds true of remittent fever.

Q. Do you recognize typho-malaria as a distinct type of disease?

A. Typho-malaria is an ambiguous word. It may mean two well recognized diseases, a combination of typhoid and malaria which is rather rare, or it may mean a malaria with typhoid symptoms, with coma and that sort of thing, or again it may mean a fever that probably has been wrongfully diagnosed. It is an ambiguous word.

Q. But if the disease represents, by proper diagnosis, the malarial parasite and the typhoid bacilli present in the same patient, that would be a rare condition would it not?

12597 A. I hear of its occurring perhaps once or twice a year, and probably I get to hear of most of the cases that are recognized. How many remain unrecognized, because not every physician makes a blood examination, can not be stated at all.

Q. What proportion of the physicians in St. Louis make blood examination?

A. I do not know.

Q. Rather a small per cent. of them?

A. No, I think now there are a good many; just what per cent. I have not any idea.

Q. You think fifty per cent. of the doctors practicing in St. Louis go to the trouble of making the blood examination, either the Widal test or the other?

A. I am sure I do not know. Among the physicians whom I personally meet, the per cent. who use the microscope is greater. These are men that do the university work. How many of those physicians that I rarely hear of make such examinations I have not the faintest idea.

Q. Do you regard congestive fever as a distinct type of a
12598 disease, and if so what is congestive fever?

A. In the old days before malaria was accurately diagnosed, the term congestive fever and congestive chill were applied to a disease which almost certainly was pernicious or fatal malaria, and when the term is used correcly that is what it means now.

Q. Do you know of any advanced scholar or authority in medicine today that recognizes congestive fever as a distinct type of disease, and pretends to tell what it is?

A. I have not got my authorities at my fingers' ends, but I am sure that any one who writes on that subject of pernicious malaria would have to mention the fact it was at one time called congestive fever.

Q. I am speaking of the science as it is viewed today?

A. And then what is the question?

Q. Do you know of any one, any expert or authority that recognizes congestive fever as a type of disease, or is able to tell what it means?

12599 A. Well, I think they would all prefer to use the word pernicious malaria as being less ambiguous.

Q. Who are some of the authorities on the question that would use terms of that kind in connection with congestive fever doctor?

A. You mean that would use the term congestive fever?

Q. That is that it would have any meaning to?

A. Well, it would have a meaning for everybody if you used it in that way, because formerly the term pernicious malaria was not used, and the term congestive fever was used. Anybody that knows the history of medcine, when he hears congestive fever mentioned, knows that it is either an old term being used or a term that means little or nothing. It might be either of those things.

Q. Is it not a fact that it conveys no meaning today when employed by physcians to the doctors who represent the advanced authorities in medicine?

A. It is ambiguous as I have stated, because the listener can not know what the speaker means.

Q. Does the speaker himself know what he is talking
12600 about, when he uses the term?

A. Perhaps so and perhaps not.

Q. Who are some of the authorities on fevers and so recognized by the medical profession in this country?

A. It is a little hard to answer that question because medicine does not go by authority. There are a great many first rate men and the men that you hear about and those that one naturally thinks of are those that happen to have written text books.

Q. Well, some of the people that have written text books?

A. There is Osler and Thayer.

Q. Have they treated in their books on congestive fever?.

A. Pernicious malaria.

Q. I am speaking of congestive fever?

A. Well, if that means anything it means pernicious malaria.

Q. I am confining my question to congestive fever?

A. And you mean whether they use the term?

Q. Whether they recognize congestive fever as a term that means anything to them?

A. From memory I should not like to say whether they
12601 use that term in their work or not.

Q. Do you recognize simple continued fever as a distinct type of disease?

A. Personally I am inclined not to, though I recognize that there are men who have practiced longer than I and have seen more fever than I who still do recognize it as a distinct type of disease.

Q. Is it not a fact that the farther away you get from the

Universities of orginal research, such as Johns Hopkins and other recognized medical schools, that the more frequently you come across the terms intermittent, remittent, typho-malaria, congestive and simple continued fevers among the practitioners?

A. I do not know. I should not think so. Of course the less educated the physicians are the more apt they would be to hedge in the matter of a diagnosis in that fashion. Whether there are more here than places in the east where the facilities for medical traning are no better, I do not know.

Q. Is it not a fact that the intermittent, remittent, and simple continued fevers are terms which are employed to 12602 characterize the nature of fevers known as either malaria or typhoid, and are not distinct types of fever so recognized by diagnosticians and clinicians?

A. I think it is likely that in the majority of cases in which these terms are used they are simply descriptive of the symptoms, but they may mean much more than merely typhoid and malaria. A great many diseases might, upon a superficial examination, produce the same sort of an impression.

Q. In the diagnosis of malaria, three distinct types of malaria are recognized by the advanced students of malaria, are they not?

A. At least three.

Q. And in the diagnosis of malaria it requires quite a degree of skill and experience to differentiate between these three types, does it not?

A. Yes sir.

Q. The ordinary practioner, by that I mean a man not connected with a hospital, or a clinician, is not as well qualified to make that diagnosis as the man who has the means at hand for doing it, like the laboratory, is he?

12603 A. Well, that portion of the diagnosis does not require a laboratory. At the medical department of the Washington University for quite a number of years, we have been turning out classes, every member of which has been trained in the ordinary methods of clinical examination, of which the microscopic diagnosis is one.

Q. How long ago has that been?

A. Well, it is a little hard to say but we have been doing it more and more thoroughly every year, but very thoroughly from four to six years.

Q. Then the doctors who were turned out prior to that time are practicing medicine without any facilities for diagnosis that the young man of today has, that is turned out? Is not that true?

A. Yes sir, they have had to acquire that skill either by means of a post graduate course or through their own efforts.

12604 Q. With a class that is turned out of a medical school what proportion of the class goes into post graduate work and what proportion starts out to practice medicine?

A. I should say that less than half went in the post graduate course.

Q. And the other half start out to practice?

A. Yes sir.

Q. So that if in the health statistics of a city the size of St. Louis there should appear in any one year as many as 200 deaths reported by physicians under the heading intermittent, remittent, typho-malaria, congestive and simple continued fevers, that would be evidence in itself of a wrong diagnosis would it not, on the part of the physicians that so reported the deaths?

Mr. Jeffries: Object to the question for the reason it is for the court to say what would be evidence.

A. Well, it is a little hard to answer that question because some of those terms to my mind can not be called diagnosis at all.

12605 Mr. Todd: Q. What would you say a doctor meant when he turned in a death certificate that the patient died from congestive fever—what did he mean by that?

A. Well, he either meant pernicious malaria or he did not know what was the matter with his patient and which of the two he meant I could not tell. If it was a good man that turned it in, a man that I knew to be good, I should assume that he had been using the old fashioned term for pernicious malaria.

Q. In the city of St. Louis do you have any cases of pernicious malaria?

A. Yes sir.

Q. How many?

A. I do not know. I have had occasion to see a number; how many more have occurred I do not know.

Q. Is pernicious malaria the tertian, the quartan or the tropical malaria?

A. That is a question that is still unsettled. It is most apt to be the tropical.

Q. Is it not a matter that has been settled?

A. No sir. There are some first rate observers who still maintain that there are five kinds of malaria, the tertian, the quartan, the tropical and two kinds of pernicious, and that the
two kinds of pernicious malaria are distinct types. I think
12606 the general trend of medical opinion is against that, but
still they have grounds for their belief. It is a question that is still open.

Q. Would the mortality from pernicious malaria in the city of St. Louis, in your opinion, be as high as fifty annually?

A. I could not say. I should be surprised if I learned that from a reliable source.

Q. Are you acquainted with the conditions of Baltimore as compared with St. Louis as to climate?

A. Not in detail. In general I know something about it, but not accurately.

Q. Do you doctors ever diagnose cases as typhoid fever and report the death as such, when as a matter of fact the patient died of something else in the city of St. Louis?

A. Do you mean I know of such a case?

Q. Yes sir.

A. I do not know of any such case, and I do not think I know of anybody who would knowingly do it. We are all apt to make mistakes.

Q. I do not mean that any doctor would diagnose a case intentionally wrong. I am assuming that of all the professions
the doctors are the most conscientious, but do doctors
12607 make mistakes of that kind?

A. I should think it would be conceivable. I do not know of any such case. I should say that that would happen rather rarely. It unquestionably could happen. Ordinarily when a patient dies of typhoid fever, unless it was an infant, the diagnosis is plain. However, I think there must be some cases where the diagnosis remains obscure to the last.

Q. Don't you think there are cases that where patients died of typhoid fever that have been diagnosed as remittent, intermittent and congestive and simple continued fevers?

A. Why, I think it is possible. I do not know.

Mr. Jeffries: You mean diagnosed and reported.

Mr. Todd: Q. You mean diagnosed and reported?

A. When a patient dies of typhoid fever he usually dies of a hemorrhage or a perforation of exhaustion; the disease has dragged on so long it has run through all its phases. It is a pretty poor diagnostician that can not in a vast majority of cases diagnose typhoid under those circumstances. Mistakes in the diagnosis of typhoid fever occur frequently, but chiefly where the disease runs a mild course and the patient does not die.

Q. What other disease could be diagnosed as intermittent, remittent and continued and congestive fevers aside from
12608 malaria?

A. Well, a great many cases of turberculosis are so diagnosed some time or other, and I have seen myself at least two cases of luekemia that were for a number of years diagnosed as malaria.

Q. If the doctors would diagnose tuberculosis under the heading of intermittent, remittent, congestive and simple continued fevers why would they not diagnose typhoid fever under that head, Doctor, the same class of doctors?

A. Oh, they would. You were speaking of deaths?

Q. I mean deaths?

A. I do not think they are very apt to diagnose deaths from tuberculosis under those heads.

Q. What heads would they diagnose tuberculosis under?

A. Ordinarily when a patient dies of that, it is pretty clear.

Q. If a patient dies of leucemia would they diagnose that death as remittent, intermittent, congestive and simple continued fever?

A. Yes sir, that might happen.

Q. What is leukemia?

A. It is a disease of the blood, producing an extraordinarily

12609 great increase in the white blood corpuscles, and accompanied by a swelling of the spleen and very frequently by a fever which may run almost any sort of a course.

Q. Is that a frequent disease, as malaria?

A. No sir.

Q. How does the mortality from leukemia compare with other diseases?

A. Well, al cases of leukemia end fatally.

Q. How does it compare with the deaths in other cases, the number of deaths?

A. I do not know. I have not looked it up.

Q. Do you have many deaths from leukemia in St. Louis, per annum?

A. There is a certain number.

Q. Well, about how many?

A. I do not know.

Q. As many as 100?

A. Well, I hardly think so, but I do not know.

Q. If there should be 100 deaths from leukemia, do you think that out of 100 doctors there would be more than one or two that would fail to diagnose it?

12610 A. Yes sir, it would be very easy to fail to diagnose that.

Q. I am taking the medical profession as it exists in the city of St. Louis?

A. Just how many cases of that would escape diagnosis I can not say. Some would certainly escape and many would be liable to.

Q. What other diseases would be characterized by the terms intermittent, remittent, congestive and continued fever, except leukemia and tuberculosis, if the patient died?

A. Well, almost any fever. I should say that in a considerable number of cases, these terms might mean the grip infection or influenza.

Q. Then when leukemia and tuberculosis and grip are reported as deaths from intermittent, remittent and simple continued fevers and congestive fever, by physicians, that is evidence of the fact of the unskillfullness of the diagnostician in making these reports is it not?

A. Not necessarily. Every one now and then one has a case that dies, and that he has not been able to diagnose. We can write on our death certificates "don't know." We do not want to make it a coroner's case, and you have to put on 12611 some diagnosis, and I suppose one might be tempted to put on a term of that sort, even if he knew it was not very specific, just because his diagnosis was not very specific.

Q. Does that practice obtain generally among physicians in St. Louis?

A. I hope not. I do not think so. I do not really know about that. It has not often been my misfortune to be put in that sort of a quandary.

Q. If the physician should make the mistake of calling tuberculosis leukemia and grip, remittent, intermittent and congestive and simple continued fevers would not those same physicians be liable to call typhoid fever, intermittent, remittent, congestive and simple continued fevers?

A. If they had a case that was obscure to the end certainly. There are cases of typhoid deaths, that remain obscure to the end but they are apt to be less frequent than deaths from those other less typical diseases. There are a great many other 12612 disease that I have not mentioned that might be called remittent, intermittent or simple continued. Any fever might be characterized in that way.

Q. Well, take a first class, up to date clinician and diagnostician, would he be fooled on tuberculosis, leukemia, grip or any of these other distinct disease, and call them intermittent, remittent, congestive and simple continued fevers?

A. I hardly think that any really first rate man would be apt to use those terms, for he would be conscious of their ambiguity.

Q. It is the careless physician that employs those terms?

A. Well, the physicians that are less up-to-date are most apt to use them, yes sir.

Q. And all physicians in St. Louis are not up-to-date?

A. Not all physicians in St. Louis are up-to-date.

RE-DIRECT-EXAMINATION

By Mr. Jeffries.

Q. Doctor, in the case of death, would typhoid fever be more or less likely to be confounded with the nonde-
12613 scripts than such as intermittent, remittent and malarial and congestive fevers?

A. More apt than what? I don't catch the question.

Q. Than grip and leukemia and nephritis?

A. I think on the whole they would be less apt to be confounded with those things than those others which are less typical in their course.

Q. Why?

A. When a patient dies from typhoid fever he usually dies frrom a hemorrhage or a perforation or from a generally exhausted condition, or a few other complications. When those occur in typhoid fever the symptomology is usually so typical in the great bulk of such cases, that the diagnosis can easily be made. The cases that are extremely difficult to diagnose, and they often escape diagnosis, are the cases that are comparatively mild. They are less apt to be typical and give the observer few points on which to base a diagnosis.

Q. That has reference to the cases and not deaths?

A. Yes sir. Those are the cases that do not die.

12614 Q. Would not the Widal test aid you in making this determination, as far as the typhoid is concerned?

A. The Widal helps in making the diagnosis.

Q. That is the obscure cases?

A. Yes sir, there are many cases in which the Widal is unnecessary, for you can make the diagnosis without.

Q. Now, if a practitioner was confounding the obscure typhoid case with malaria, intermittent, remittent and congestive fever, the Widal test would come to his assistance in making the proper diagnosis?

A. Yes sir, no question about it.

Q. Now, then, would this Widal test throw any light upon that case in the event that the patient was afflicted with any of these other diseases, such as leukmia and grip and nephritis?

A. I did not say anything about nephritis.

Q. I mean tuberculosis?

A. Yes sir, in such a case the Widal reaction would be apt to be negative and typhoid could be disregarded as one of the possibilities. Is that what you meant?

12615 That is it exactly.

Q. So then instead of by the use of the Widal test of its being typhoid it may be something else?

A. Oh, certainly, when we do the Widal test in our general work, I should say the result is negative ten times to where it is positive once. As it is comparatively a simple thing to do, the Widal test is made in all cases, where there is the faintest suspicion of typhoid. I do a far greater number of negative Widals than of positive ones.

Q. In that case you have to look to some other source for the disease?

A. Either that or perhaps the blood was taken in too early a stage of the typhoid. At any rate, so far as it goes, a negative Widal speaks against positive diagnosis of typhoid. Usually it means there is something else wrong with the patient.

Q. At what ages are persons most likely to contract typhoid fever?

12616 A. On the whole it is a disease of maturity and middle age, though both the very old and the very young do have it. Just how frequent it is in infancy is still a matter of considerable dispute.

Mr. Todd: Q. In regard to the symptoms of the disease of typhoid, that depends largely upon the skill of the physician that is attending in order to properly interpret that, does it not?

A. Yes sir, the more skillful the physician the less difficulty he would have in interpreting the symptoms of a disease.

Q. Assume that a patient had typhoid fever, and it was wrongly diagnosed as intermittent fever, and the doctor permitted that patient to eat solid food which resulted in perforation followed by peritonitis, would that doctor be skilled enough to say that that patient died with typhoid fever because he happened to die with a hemorrhage and peritonitis?

A. I can not tell because I do not know how skillfull a hypothetical physician might be. It is hard for me to conceive of a man who has a case of fever of an obscure type such as such a diagnosis would presuppose, that lasts for some time, and then ends in death by perforation, and still at the very last 12617 could not diagnose typhoid. I do not know of any such physician. There must be few.

Q. Do you really think there are few?

A. Yes sir.

Q. Are you acquainted with the report made by Dr. Vaughan of the typhoid condition at Chickamauga during the Spanish-American War, in the hospitals there?

A. I read it at the time, but I do not remember it very precisely.

Q. When the physicians diagnosed something like 400 soldiers as being afflicted with intermittent, remittent, typho-malaria and congestive and simple continued fevers, and by a clinical diagnosis conducted by Professor Vaughan of Ann Arbor the 400 turned out to be typhoid fever?

A. No, I did not read that.

Q. If such is the fact as sworn to by Professor Vaughan and also reported to the United States Government?

A. Well, I should say perhaps in a thing of that sort, 12618 with everything crowded, and the physicians worked within an inch of their lives, perhaps they could not give proper attention to diagnosis.

Q. Did you ever know of a case of typhoid fever where the patient was permitted to eat solid food?

A. Yes sir, some of the best men do that. Dr. Shattuck of Boston permits his typhoid patients to eat solid food and he is one of the leaders of the medical profession in this country.

Q. For treatment?

A. Yes sir, he cuts out the most indigestible food, but he permits such patients to eat solid food right along; however, he keeps them quiet.

Q. Is that accepted by experts of the medical profession as the proper food to give a typhoid patient?

A. There is a good deal of divergence of opinion on that point. I should say that perhaps the majority incline the other way, but certainly some of the very good men agree with Shattuck.

Q. If there is a perforation of the bowels of a typhoid patient that causes peritonitis does it not?

A. Yes sir, that is unless the bit of the gut happens to be 12619 lying over the perforation and closes it up. When it is fatal it is because it causes peritonitis.

Q. Is it your opinion that the ordinary doctors, generally speaking, are sufficiently skilled as to make very few mistakes in the diagnosis of the deaths from typhoid fever?

A. Yes sir, I think I can answer that by yes. I think the mistakes must be few. Certainly as compared with many other diseases.

ALBERT E. TAUSSIG.

ADJOURNED until 10:00 A. M., Tuesday, May 24, 1904.

10:00 A. M., Tuesday, May 24, 1904.

12620 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

DR. CHARLES H. GOODMANN,

a witness called on behalf of the complâinant, being duly sworn by the Commiessioner, was examined in chief by Mr. Jeffries, and testified as follows:

Q. Doctor, state your full name, residence and profession?

A. Charles H. Goodmann; 3329 Washington Avenue, physician.

Q. Where were you educated in your profession, Doctor?

A. In St. Louis, and Philadelphia.

Q. Had you previously received an academic training?

A. I graduated at Yale.

Q. What year?

A. 1867.

Q. That is Yale University?

12621 A. Yes sir, it was Yale College at that time.

Q. And what colleges in St. Louis and Philadelphia?

A. At the Homeopathic Medical College of Missouri in St. Louis, and the Hahnemann Medical College in Philadelphia.

Q. How long have you been practicing medicine in St. Louis?

A. About thirty-five years.

Q. Have you occupied a chair in any medical college?

A. Yes sir, I have taught Theory and Practice for about five years at The Homeopathic Medical College of Missouri.

Q. What was your position in that college?

A. Professor of Theory and Practice.

Q. Are you connected with any hospital in St. Louis?

A. St. Louis Children's hospital. I am attending physician and member of the staff.

Q. How long have you been connected with that hospital?

A. Since its foundation, about twenty years any way. Twenty-two years or maybe twenty-three, I have for-
12622 gotten; between twenty and twenty-five years.

Q. Are you a member of any medical Society?

A. State and local, as well as the National.

Q. Have you been an officer of any of the medical societies?

A. City Medical Association.

Q. What was your office?

A. President.

Q. And the St. Louis Medical Association?

A. The St. Louis Homeopathic Medical Association.

Q. Are you acquainted, Doctor, with the disease known as typhoid fever?

A. I have some knowledge of it.

Q. Do you treat that disease in your private practice?

A. I do.

Q. The general practice?

A. I do.

Q. Are you acquainted, Doctor, with what is known as the Widal test?

12623 A. Yes sir.

Q. Do you use that in your practice?

A. I do.

Q. Doctor, what is the real object of the Widal test?

A. To establish the diagnosis.

Q. With reference to the particular disease known as typhoid fever, what is the necessity of obtaining a diagnosis?

A. Because it might be confounded with other diseases in the beginning.

Q. And the real object is to obtain an early diagnosis?

A. An early diagnosis, in order to secure a proper treatment of the case.

Q. Is typhoid fever such a disease as requires early treatment in order to better insure favorable results?

A. Yes sir, I think so.

Q. Doctor, taking into consideration the fact that by the use of the Widal test an early diagnosis may be made which will determine whether or not the disease is true typhoid, and taking also into consideration the fact that typhoid is a 12624 disease which if treated in its early stages is less likely to become fatal, what effect, if any, has this Widal test had upon the typhoid mortality cases or list?

A. I think it has enabled physicians who have had those cases to distinguish between deaths from typhoid and deaths from other causes.

Q. Cases of death?

A. Cases I mean.

Q. By reason of this ability to give proper early treatment, has it had any effect in lessening or increasing the number of deaths from typhoid in your judgment?

A. I think it has enabled physicians perhaps to place the causes of death to typhoid that possibly they might not have done otherwise.

Q. Would it not also have enabled physicians to have ascribed deaths to some other cause than typhoid?

A. Yes sir, that is true too.

Q. And therefore to have eliminated deaths as caused by typhoid from the typhoid list?

A. Yes sir.

12625 Q. Going back now, Doctor, to the results that are actually obtained by reason of the physician being able to treat the case as typhoid in the earlier stages of that disease, state whether or not in your opinion this earlier treatment upon the part of the physicians who have used the Widal test has brought about conditions which resulted in a less number of deaths from typhoid than would have resulted had the Widal test not been used, and the cases treated alone, without the knowledge on the part of the physician as to the true disease with which the patient was afflicted?

A. Do you mean the recognition of the disease or the mortality?

Q. I mean being able to recognize the disease in its earlier stages, the physician has been enabled to give the patient such treatment which otherwise would have been a malignant case?

A. I believe that.

12626 Q. And therefore the death rate would be, by means of the use of the Widal test, as the fatality of the typhoid has been somewhat reduced?

A. Yes sir, I believe that.

Q. Doctor, state whether or not the Widal test as a general proposition is used for determining the cause of death, or to aid the physician in making an early diagnosis of the case?

A. In making an early diagnosis.

Q. State whether or not as a general proposition when a patient dies of typhoid fever there is any difficulty in making out the cause of death?

A. No sir, not as a general thing.

Q. What is your reason, Doctor, for stating as a cause of death from typhoid fever there is very little trouble in properly diagnosing the cause of that death?

A. That might be a matter of experience. I do not think I should have any trouble in diagnosing a case that had died of typhoid fever, after death, if I had the history of the case, and the general run of the symptoms, such as the continuance of the
fever, the duration, the temperature curve, and the at-
12627 tending symptoms that go with it. I believe I could
diagnose a case of typhoid fever even without the test, after death.

Q. Are not the symptoms of the patient, a few days before death, such as would enable the ordinary physician to determine it was typhoid, if the patient died with the disease?

A. Yes sir, if he died with the disease. Then I should include under the general run of the symptoms the course of the symptoms.

Q. Doctor, what effect has the fact that letters and circulars have been sent out to you by the health department of

St. Louis, asking you to report promptly all deaths from typhoid and other contagious diseases had upon you in making these reports?

MR. TODD: Object to the question for the reason that it is not rebuttal and therefore incompetent, irrelevant and 12628 immaterial, and no charge is made against this physician in defendants' case.

A. It made no difference at all with me.

MR. JEFFRIES: Q. Are you acquainted with the members of your profession in St. Louis, generally?

A. Pretty generally.

Q. Have you heard them discuss in a general way the fact that they had received these circulars, and that the circulars had been sent out, of the character mentioned?

A. No sir.

Q. What effect had the opening of the drainage canal had upon you in making these reports?

MR. TODD: Object to the question for the same reasons as heretofore stated.

A. None at all. I simply watched with curiosity to see what the increase in typhoid might be at the time, but I do not even remember now what the results were.

Q. State whether or not in conversation with the members of your profession in the meetings and societies which 12629 were held, that it was generally discussed among the members of the fraternity that they should be very prompt in the future in sending out these reports from the health department?

MR. TODD: Objected to for the reason that whatever took place in any of the societies of doctors is not competent evidence and is not rebuttal of anything that has been introduced in defense and is therefore hearsay which makes it incompetent, irrelevant and immaterial.

A. No, I heard no such discussion at all.

MR. JEFFRIES: Q. Doctor, are you acquainted with the development in the recommendations on the part of the physicians and the use of domestic filters in the city of St. Louis?

MR. TODD: Object to the question for the same reason that it is not rebuttal and is therefore incompetent, irrelevant and immaterial.

12630 A. Yes sir, in a general way. During the times that we have had epidemics or had an increase of typhoid fever here, there has been a general upheaval in the families where I visit, and a great deal of talk about the water being a source of typhoid fever, and physicians recommend filtration at first, and then that did not seem to satisfy the people, and they were advising them to boil the water and that was done, and it did create quite a little talk I know among my own circle of patients. I was appealed to a number of times to know what they should do, whether filter the water or boil it, and it did create some discussion at two or three periods where we had an increase of typhoid here.

MR. TODD: I move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. State whether or not the physicians generally throughout the city of St. Louis recommend to their patients and families under their care the filtration and boiling of water?

MR. TODD: Object to the question for the same reasons as heretofore stated. 12631

A. Yes sir, they did so far as my acquaintance with the physicians goes.

MR. TODD: I move to strike out the answer for the same reason.

MR. JEFFRIES: Q. Is it not a fact, Doctor, that this recommendation on the part of the physicians of St. Louis is more general now than it was six or eight years ago?

A. Yes sir.

MR. TODD: I object to the question for the same reasons as heretofore stated, and move to strike out the answer for the same reason.

MR. JEFFRIES: Q. State whether or not it is a fact that the domestic filters are in more general use now than six or eight years ago?

MR. TODD: Object to the question for the same reason as heretofore stated.

A. Unquestionably so.

MR. TODD: I move to strike out the answer for the

12632 same reason.

MR. JEFFRIES: Q. State whether or not the boiling of water is more generally practiced now than it was six or eight years ago, for drinking and domestic purposes?

MR. TODD: Object to the question for the same reasons as heretofore stated.

A. It is.

MR. TODD: Move to strike out the answer for the same reasons.

MR. JEFFRIES: Q. Doctor, state whether or not domestic filters have proven satisfactory in all events?

MR. TODD: Object to the question for the same reasons as heretofore stated.

A. So far as the mere clearing of the water is concerned, they are satisfactory, but as to the clearing it of the germs or rendering it any more safely drinkable, I have my doubts.

MR. TODD: Move to strike out the answer for the same reasons.

MR. JEFFRIES: Q. Doctor, are you acquainted with what is known as the epidemic in November and De-

12633 cember, 1899, in St. Louis?

A. I am.

Q. That was a typhoid epidemic?

A. Yes sir.

Q. Do you know, Doctor, whether or not that was localized or general throughout the city?

A. Localized.

Q. In what locality did that epidemic occur?

MR. TODD: Object to the question on the ground that the epidemic of 1899 has been gone into in chief by complainant's witnesses, and it is not rebuttal of anything that has been offered by the defendant, and is new matter as far as this rebuttal evidence is concerned, and is incompetent, irrelevant and immaterial.

Q. It was in the west end portion of the city.

MR. TODD: I move to strike out the answer for the same reasons stated in the objection to the question, MR. JEFFRIES: Q. Did it extend to any other portion of the city?

12634 MR. TODD: Object to the question for the same reasons as heretofore stated.

A. Not in general. It was a subject of remark at the time that it was confined to the west end, in the better resident portion of the city.

MR. TODD: Move to strike out the answer for the same reason heretofore stated.

MR. JEFFRIES: Q. In other words, physicians expressed surprise that it was not general?

A. Yes, it was not general.

MR. TODD: Object to the question as leading and incompetent, irrelevant and immaterial, and move to strike out the answer for the reasons stated.

MR. JEFFRIES: Q. Doctor, at what age are people most susceptible to typhoid fever?

A. From ten years up.

Q. Do children and old people—are children and old people as subject to that disease as middle aged people?

A. Not as far as I have observed.

12635 Q. State whether or not, Doctor, typhoid is more prevalent in this latitude during the summer months or the winter months?

A. Of the two seasons I should say, if you express it that way, the winter months. We have it more in the fall or early spring, although the worst cases I have seen personally have been in the middle of winter.

Q. As a general proposition it is in the warmer seasons?

A. Yes sir, the change of seasons, summer to fall and spring to summer.

CROSS-EXAMINATION, by Mr. Todd:

Q. Doctor, are homeopathic physicians regarded as physicians in good standing?

MR. JEFFRIES: Object to the question.

MR. TODD: You have one witness on your side that swore they were not, and I wanted to prove they were.

MR. JEFFRIES: It was drawn out on cross-examination. It was his individual opinion.

12636 A. That is a hard question to answer, Mr. Todd, because there is so much involved in it. By the more liberal men of the opposing schools, I believe that they today have a proper recognition. Among the mass, I believe they are not so regarded.

Q. By the mass, what do you mean?

A. I mean the average physician, the old school physician. That is where the opposition comes from.

Q. Do you mean the alopaths?

A. I mean the alopaths, the alopathic schools of medicine.

Q. In homeopathy, the diagnosis of disease is based upon the totality of the symptoms?

A. Entirely.

Q. And in the treatment of diseases, the symptoms are treated?

A. Certainly; that is the basis of our prescriptions and the totality of the symptoms, for the treatment as well as the recognition of the disease.

Q. Do homeopathists recognize the germ theory of disease?

12637 A. They are divided on that.

Q. In what way, Doctor?

A. Some assert that the germ is the result of the disease and not the cause of it, or an accompaniment of the disease and not the cause of it.

Q. Is that view held exclusively by homeopathists?

A. No sir, I have seen statements in old school journals that certain members hold to that belief too.

Q. When you state that you would have no trouble in determining a death from typhoid fever, do you mean that the determination of typhoid fever deaths is a matter that all physicians, that any persons, regardless of their qualifications, so long as they possess a license to practice medicine, can determine?

A. That might be assuming a good deal for myself.

Q. I am asking you for your opinion as a doctor?

A. No, I do not think—

Q. Without fear of offending the fraternity?

A. I do not care anything about the fraternity, but I do believe that a young practitioner, a man who had a lim-
12638 ited experience, possibly could be mistaken. It is only an individual opinion of mine, that I might be able to recognize it.

Q. Do you believe that experience is valuable to a doctor in diagnosing typhoid fever?

A. I do believe experience is.

Q. In the number of doctors turned out from our medical schools, what proportion enter practice with any clinical experience in hospitals?

A. A comparatively small proportion.

Q. Would not the doctors that are turned out from our medical colleges be truer diagnosticians if they had supplemented their medical education by an experience in hospital work?

A. Undoubtedly.

Q. When a young doctor starts out to practice medicine and has had no experience in hospital work, in carrying cases of typhoid fever from their inception to the convalescent stage, how are they able to properly diagnose a case of typhoid fever except by mere pictures in the medical books, with a case?

A. They can not in any other way.

12639 Q. Is it not the common experience of older physicians that young doctors when turned out of a medical college while they are able to pass the examination from the text books, are inexperienced in the treating of cases?

A. That is undoubtedly so.

Q. Inexperienced?

A. Yes sir.

Q. Doctor, when you mean that any ordinary physician can diagnose a death from typhoid fever, do you include in that men of equal standing with yourself, or the young men that have gone out from the medical college without any hospital experience in the last five or six years?

A. Only men of equal standing with myself.

Q. It is a difficult matter for the very best of doctors to diagnose a case of typhoid fever, is it not?

A. At times.

Q. Are you acquainted with Senator Hanna's case?

A. Only what I have read in the paper about it and that was very desultory.

Q. He had typhoid fever three or four weeks before it was pronounced so by the leading doctors that treated him?

12640 A. Yes sir.

Q. In the beginning there was a difference of opinion as to whether or not he had typhoid, is that not true?

A. Yes sir.

Q. And if a case of typhoid fever would confound men of the standing of those doctors, is it not reasonable to suppose that among the ordinary practitioners in the city of St. Louis that cases of typhoid fever would confound the local doctors?

A. Yes.

Q. Do you recognize as a distinct type of disease intermittent fever?

A. Yes.

Q. Do you recognize, as a distinct type of disease, remittent fever?

A. I do not.

Q. Do you recognize typhoid malaria as a distinct type of a disease?

A. I do not. That is a term that is very obscure. I do not recognize that as a distinct form of disease.

12641 Q. Do you know of any case that came under your experience where the malarial parasite and typhoid germ have been found in the same patient at the same time?

A. Not in my own personal experience.

Q. Do you recognize congestive fever as a distinct type of a disease?

A. No sir, I do not.

Q. What does the word congestive fever convey to your mind?

A. I should understand that form of fever which might be characterized by local congestion of any portion of the body that was subject to it.

Q. Do you recognize simple continued fever as a distinct type of a disease?

A. No. No sir, I do not.

Q. These terms are characteristic of certain diseases rather than the diseases themselves, is that not right?

A. That is true.

12642 Q. It may be typhoid, it may be malaria, or some other disease which has a remittent, intermittent, congestive or continued fever symptom?

A. Yes sir.

Q. What other diseases are as prevalent in the city of St. Louis as malaria and typhoid, which possess these symptoms?

A. None that I know of.

Q. You would not regard trichinosis as a prevalent disease in the city of St. Louis, would you, Doctor?

A. No sir.

Q. In the diagnosis of tuberculosis, is there any more difficulty in diagnosing that disease than the disease of typhoid fever?

A. You mean in the early stages?

Q. From its beginning to its fatality?

A. No sir.

Q. Would a doctor be more likely to confound tuberculosis with typhoid fever than typhoid fever with tuberculosis?

A. I do not see how he could do that.

Q. Would the inexperienced physician, without hospital training, be liable to confound typhoid fever with malarial fever?

12643 A. He might; yes sir.

Q. You stated that you were acquainted with the epidemics in the city of St. Louis?

A. I am.

Q. Have you studied the mortality statistics of the city of St. Louis?

A. No sir, not to any extent.

Q. If in the health reports of the city of St. Louis there should appear tabulated as deaths occurring from intermittent, remittent, typho-malaria, congestive and simple continued fevers, a number of deaths in excess of the number of deaths from typhoid fever, and as you stated you do not regard intermittent, remittent, typho-malaria, congestive and simple continued fevers as distinct types of disease, what, in your opinion, did the people so charged with dieing under that head of remittent, intermittent, typho-malaria, congestive and simple continued fevers die of?

A. They might have died of typhoid fever. They must have been confounding the terms, or confounded the
12644 diagnosis of cases, I should think.

Q. Do you know of any such fatality from malarial fever as to justify placing those deaths under the head of malarial fever?

A. No sir, I do not.

Q. You are acquainted with the epidemic of 1892, are you not?

A. 1892?

Q. When the contagion is supposed to have come from Bissell's Point Creek up above the waterworks?

A. Yes sir, I remember that.

Q. In 1891, the year before that, there were 165 deaths in the city of St. Louis from typhoid fever, and 296 deaths under the heading intermittent, remittent, congestive, typho-malarial, and simple continued fevers; in 1892, the year of special epidemic, there were 441 deaths from typhoid fever and 326 deaths from intermittent, remittent, typho-malarial, congestive and simple continued fevers; in the year 1893, following the epidemic there were 215 deaths from typhoid fever and 284 deaths from intermittent, remittent, typho-malaria, congestive and simple continued fevers. Comparing the number of deaths from typhoid with the number of deaths from intermittent, re-
12645 mittent, congestive, typho-malarial, and simple continued fevers, do not those statistics show that the doctors in reporting typhoid conditions in the city of St. Louis reported cases of typhoid deaths under the remittent, intermittent, typho-malarial, congestive and simple continued columns?

A. Yes sir, I believe they did at that time.

Q. That was before the day of the Widal test?

A. Yes sir.

Q. Then the board of health reports showed that in 1894 there were 171 deaths from typhoid fever and 179 deaths under the typho-malaria column; in 1895 there were 107 and 135, respectively; in 1896 there were 106 and 177 respectively, in 1897 there were 125 and 172, respectively; in 1898 there were 95 and 134, respectively. In the number of deaths appearing as being reported by the physicians of St. Louis to the health department under the heading of intermittent, remittent, typho-malaria, congestive and simple continued fever be accounted for in any other way than that typhoid fever deaths were wrongfully diagnosed as something else, and so reported, in your opinion, assuming that the figures that I have quoted have 12646 been sworn to and verified as true in the record in this case?

A. Well, so far as they are true, I certainly do. On the supposition that these figures were correct, I will say that the reports may have confounded diseases. Those that were reported as typho-malaria might have been typhoid, or typho-malaria, congestive, remittent or intermittent.

Q. But assuming that these statistics which I have quoted are properly compiled from the reports of physicians placed in the health department of the city of St. Louis, and published in their official reports?

A. Yes sir.

Q. And assume that the board of health of the city of St. Louis only had the compiling of the statistics, not making out the diagnosis—that came from the doctors—can 12647 the number of deaths reported under the heading intermittent, remittent, typho-malaria and congestive fever column be accounted for in any other way than that typhoid fever has been wrongfully diagnosed under these various headings?

A. No sir.

Q. In the year 1899, since the Widal test—if in those same health reports that have been verified here in evidence and admitted without question on both sides, there should appear 101 deaths from typhoid fever and 148 deaths under the typho-malaria group, notwithstanding the Widal test, can you account for the 148 deaths from typho-malaria under any other supposition than that typhoid fever has been wrongfully diagnosed under some of these different headings?

A. No, I can not unless that possibly those physicians might have been mistaken in their diagnosis and not used the Widal test.

12648 Q. Is the Widal test used by all the doctors practicing medicine in the city of St. Louis?

A. It is used by some. I do not believe it is used by all.

Q. Eliminate the doctors in St. Louis connected with hospitals and medical schools and medical associations, do you believe that the rest of the doctors employ that test in the differentiation of disease?

A. I can not answer that. I do not know, but I believe all reputable physicians, by that I mean physicians of any standing, who have a practice among intelligent people, do. I think they are compelled to do it.

Q. But the medical profession is like any other profession it has men that stand prominently at the top in St. Louis?

A. Yes sir.

Q. Then comes the next strain of doctors?

A. Yes sir.

Q. And then the lower strain, that is where the greatest number are found, is it not?

A. Yes sir.

Q. Now, in 1900 a circular letter was sent out by the health department to all the physicians?

12649 A. Yes sir.

Q. At the time that that circular was sent out, do you remember of the public press of the city discussing the question of the opening of the drainage canal and its effect upon the public health of the citizens of St. Louis?

A. No sir, I can not remember the dates. I know there was such a discussion, but I can not recall whether it was at that particular time or not.

Q. About the time of the opening of the canal?

A. Yes sir.

Q. The canal was opened on January 17, 1900?

A. Yes sir.

Q. Now, while that letter had no effect upon you, are you prepared to state that it had no effect upon any of the doctors that practiced in the city of St. Louis?

A. No sir.

Q. If you would compare the typhoid condition for four years before the opening of the drainage canal with the typho-

malaria condition with the four years since the opening of the
canal with the typhoid, malaria condition, which I will
12650 read to you, as the figures taken from the board of
health reports and sworn to as follows:

	Typhoid fever.	Typho malaria.
1896	106	177
1897	175	172
1898	95	134
1899	131	148
1900	168	112
1901	198	80
1902	222	102
1903	288	91

After considering the typho-malaria column for four years previous to 1900 and the typho-malaria column for the four years subsequent to 1900, the typhoid death column for the four years previous and the four years subsequent, can you account for the decrease in the typho-malaria column and the increase in the typhoid fever column in any way except that the fevers which had heretofore been diagnosed as intermittent, remittent, typho-malaria, congestive and simple continued fevers have been
diagnosed as typhoid fever and placed in the typhoid
12651 fever column, when heretofore they were placed in the
typho-malaria column prior to 1900?

A. No sir.

Q. Would you say, interpreting this statistical deaths from the St. Louis health reports, that if a letter had been sent out by Dr. Teichmann, who was connected with the city health department to all the doctors in the city, asking for a report on typhoid fever cases and mortality, under penalty, that the effect of such a letter is not manifest in the statistics that are published by the city of St. Louis health department?

MR. JEFFRIES: Object to the question for the reason it is for the court to determine whether it is manifest and not for this witness.

A. Yes sir, I think if there was a penalty, the doctors would make a report accurately.

MR. TODD: Q. And does that report manifest itself in your opinion in the statistics?

MR. JEFFRIES: Objected to for the same reason.

A. Was there to your knowledge, if I may ask you a question before replying, any penalty attached in that circular letter? I do not recall such a one as that.

12652 MR. TODD: Q. According to the testimony of Dr. Teichmann, such a letter was sent out calling attention to the provision of the ordinance that contained the penalty.

A. If that was sent at the time, I do not believe, as stated before, that that letter made any particular impression on the physicians at all, and from what I know of it personally. and the physicians, I can not see how that would influence the physicians at the present time.

Q. Then how do you account, Doctor, for the large number of cases of reported deaths for four years previous under the typho-malaria, intermittent, remittent, congestive and simple continued fever columns and the small number since 1900?

MR. JEFFRIES: I object to the question for the reason that there is no evidence showing that any such number of cases was ever reported to the board of health, certainly not on the part of the complainant.

MR. TODD: In reply will state that Professor Jordan testified to the figures which I am using as coming from the official reports of the board of health of the city of St. Louis and by an agreement between counsel for complainant and counsel for defendant the board of health reports were not questioned as to their admissibility, and that they were not 12653 required to be verified by counsel, and the record in this case will show it, and the statement by counsel that objects that he offered no objection as to the fact that they were the official health reports of the city of St. Louis.

MR. JEFFRIES: In reply to the statement of counsel I will say that as to the number of deaths from typhoid fever reported in the published health reports, and which was referred to by complainant, no question was made as to the authenticity or correctness thereof, and that as to the introduction of the records showing the number of cases of remittent, intermittent, simple continued fever, no objection was made to the introduction of the published health report as such, but no agreement was ever entered into or made by counsel for complainant

that what is shown in such report represented true conditions in the office of the board of health of the city of St. Louis, and in the mortuary office thereof, and counsel at the time that Professor Jordan and other witnesses for defendant were
12654 testifying specifically asked each of these witnesses if they did not obtain that information with reference to the remittent, intermittent, simple continued and congestive fevers from the published health report and that they had not at that time or at any other time examined the original books in the office of the board of health of the city of St. Louis and particularly the mortuary office thereof.

MR. TODD: For the information of counsel, and to call the attention of the court to the fact when Dr. Teichmann was on the stand, I had him identify the official records of the health department of the city of St. Louis and offered them in evidence as an exhibit for identification and it was then and there agreed by counsel for both sides, as the record will disclose what agreement was entered into in regard to the health reports. When counsel for complainant made use of the health report it was objected to, and if the objection urged by counsel for complainant against the defendant in this case is valid then the defendants' objection is equally good or valid against complainant, and all these matters appear in the record in this case.

12655 MR. JEFFRIES: I will state that the offer was made and no objection was made to the formality of the introduction of the health reports so far as it related at that time to typhoid fever, by counsel for the defendant. No offer was made at that time to make any showing as to the number of deaths that had occurred from any other disease or any disease other than from typhoid fever and while in truth and in fact the original books in the mortuary office of the board of health disclose conditions that, if anything, are against complainant so far as is displayed in the published health report, yet we are willing to concede and do concede that point to the defendant so far as typhoid fever is concerned, as made by the counsel, that no agreement has ever been made upon the part of the complainant with respondent to the correctness of the figures set out in the published report of the board of health upon the total number of deaths reported or carried for the various years for remittent, intermittent, congestive and simple continued fevers, or any other disease than typhoid fever.

MR. TODD: Why complainant did not offer in his case the number of deaths under intermittent, remittent, typho-malaria, and congestive fevers is patent to the court and 12656 needs no remark from me. As far as I understand that the board of health reports published by authority of the city health department would be permitted on the part of defendant to use those reports without the necessity of verification, I contend that such an agreement was made, and the record in this case will disclose it, and if it was not put into the record I still assert that such an agreement was made, whether it is repudiated or not, is another question, but I am satisfied that the records will show at the time that these books were used, such an admission by counsel and the purpose and objects conceded by him as to the use that defendants could make of these reports.

MR. JEFFRIES: In response to what counsel has said, I will say that at the time that the published health reports of the city of St. Louis were introduced for the purpose of showing the total number of deaths occurring in that city during the various years, from typhoid fever, that the original mortuary records had been compared with their health reports by the State of Missouri for the purpose of determining whether or not the facts set forth in that report, so far as typhoid fever is concerned, was correct, and finding that it was correct in 12657 that report, the published report, because it was more convenient to do so. Then as to the question of remittent, intermittent, typho-malaria, congestive and simple continued fevers and other diseases, they were injected into this case by respondent, were not referred to by the complainant and there would have been and was no objection at the time of the introduction of the typhoid statistics and making that examination or comparison for the purpose of determining the accuracy of the published health report, and that the admissions that have been made in this case so far as the published board of health reports are concerned, bearing in mind that they were admitted at the time as evidence as to typhoid conditions were being considered, that the agreement went only to typhoid conditions, and the complainant having no idea at the time that any other disease would be brought into consideration defendants not having raised the point that they are now raising, did not, as heretofore stated, make a comparison of the original record with the published record, and during the course of the examination of the defendants' witnesses specifically called their attention to the fact that they were testifying from the 12658 published reports, and asked them each that question, and they each answered that they had never seen and never examined the original records with reference to these nondescript diseases in the mortuary office of the city health department of the city of St. Louis, and I make this statement in order to show to the court and to counsel that I am not undertaking to take advantage of him, as he seems to contend in his statement.

MR. TODD: In reply will state that aside from any agreement of the kind or character, I contend that the published official reports of the board of health of the city of St. Louis is competent evidence, and as such have been employed by the defendants in this case.

MR. JEFFRIES: I will state that while under circumstances they might be competent, yet they are never conclusive evidence of anything stated therein, nor are they under any circumstances the best evidence.

MR. TODD: Counsel for defendant submits it is a matter for the court to pass upon.

Q. Question read.

A. Mistaken diagnosis.

12659 MR. TODD: Q. In what way was the mistake in diagnosis in your opinion?

A. Classifying those diseases under typho-malaria that were probably typhoid.

MR. JEFFRIES: Q. Doctor, are not those diseases known and recorded as intermittent, remittent, typho-malaria, congestive and simple continued fevers confounded with other diseases than typhoid?

A. Yes sir, they could be.

Q. And more particularly is that not true with reference to these inexperienced and young physicians which Mr. Todd has referred to?

A. Yes sir.

Q. But, Doctor, a young physician is not able to diagnose a true case of typhoid fever as typhoid; is he not just as liable because of his inexperience to attribute the cause of death to a various number of diseases as to one particular disease?

A. Certainly.

Q. Then if a young and inexperienced physician with the well known fact which is taught in all of the medical books and journals and profession that typhoid disease is such a 12660 disease that when death occurs its symptoms are generally well known and are well to be observed within the last two or three days prior to death then any young and inexperienced physician would be more liable to report that death as true typhoid than he would as intermittent, remittent, congestive or simple continued fever?

A. I believe that would be true of the more recent graduates from the medical colleges, since they have raised the standard of education and extended the course from two to four years, I think they are better fitted to diagnose disease than the graduates prior to that time who had only a two year course.

Q. Is it not a fact, Doctor, that the disease known as typhoid fever, when it becomes fatal, as a general proposition, has such symptoms that an honest, intelligent, progressive physician can without much difficulty determine the cause?

A. Yes, I should think he could, if it were so pronounced as that.

Q. As a general proposition does it not become very pronounced in case of death?

A. Yes sir.

Q. Is it not generally true that when there is a confounding of cases in the diagnosis, and when physicians are unable to determine with precision the character of the disease, 12661 that such inability and such confounding generally occur in cases of typhoid rather than in deaths from typhoid?

A. Yes.

Q. As a general proposition, Doctor, is it not true that when families in St. Louis, of the intelligent class, and the general run of people in St. Louis, when they have a member of the family afflicted with the disease that takes them so low unto death as typhoid fever that they secure the advice of competent physicians?

A. That is generally supposed to be so, yes sir.

Q. Doctor, in the case of Senator Hanna, there is no question but what he died of typhoid fever, is there, in the mind of the general public?

A. I think not. I believe that is the generally accepted opinion.

Q. For the last three days prior to his death there was no question as to the diagnosis of the disease?

A. I believe not according to the statements.

Q. And that is equally true in all cases of death from typhoid?

A. As pronounced as that, yes sir.

12662 Q. If Senator Hanna had been afflicted with a light attack of typhoid fever, it then would have been possible, might it not, for him to have recovered, without the physicians ever having known the true disease, that he was afflicted with?

A. Yes sir, that is a possible case.

MR. TODD: Q. Doctor, if a doctor treats a patient in St. Louis for a disease which he calls congestive fever, and that patient dies, would he issue a certificate as typhoid fever or a certificate of congestive fever?

A. I do not think I can answer that. I do not know what a man would do under those circumstances.

Q. If he treated a patient for a disease which he called intermittent, remittent, typho-malaria, congestive or simple continued fevers, any one of these, and the patient should die, would he not issue the death certificate for the disease he thought the man had?

A. I should think so.

Q. And is not that true, evidenced by the fact that doctors do do that because of the number of deaths reported in the board

of health reports of the city of St. Louis, as occurring
12663 under those different heads?

A. Yes sir.

C. H. GOODMAN, M. D.

12664 DR. HERBERT E. SMITH

a witness called on behalf of the complainant, being duly sworn by the Commissioner, was examined in chief by Mr. Jeffries, and testified as follows:

Q. What is your name, Doctor?

A. Herbert E. Smith.

Q. Your residence and profession?

A. New Haven, Connecticut; Dean of the Yale Medical School.

Q. Yale Medical School?

A. Yes sir.

Q. Is that the Medical School of Yale University?

A. It is the Medical Department of the Yale University.

Q. Doctor, where did you receive your educational training, aside from your professional training?

A. After the usual college preparatory course in the Hartford High School, I entered the Sheffield Scientific School of the Yale University, in the chemical and biological course which is designed as a preparation for the study of medicine; then in the Medical Department of the Yale University where I was laboratory assistant to Professor Benjamin Sillmann. Then I went to the University of Pennsylvania, in Philadelphia and re-
12665 ceived the degree of Doctor of Medicine, there in 1882. Then I went to the Yale Medical School as a laboratory assistant to Dr. Benjamin Sillmann. At the end of that year I was appointed Lecturer in Chemistry in that department, and retained that position for three years, meanwhile doing, besides my teaching there, a certain amount of research work in Chemistry in the Sheffield School and also worked at Heidelberg, Germany, where I did some special chemical work at the University there. After the death of Professor Sillmann I was appointed Professor of Chemistry in the Medical Faculty of Yale, which position I still hold. This was in 1885. Shortly

after that I was appointed Dean of the Medical Faculty, which position I still hold.

Along in the latter part of the 80's I was appointed by the Governor, one of the State Chemists for Connecticut, and became interested in water works and water analytical work, being connected with the Connecticut State Board of Health in the work which they were pursuing on Rivers Pollution in the State of Connecticut, and the examination of water supplies.

After being associated with the Board for some time I was appointed Chemist of the Board and now, for a matter of about fourteen years, I have had immediate charge of all the 12666 chemical work and bacteriological work which the board has done on the matter of Rivers Pollution and examination of sewage and sewage effluent and drinking water.

Q. Did you receive a degree of any kind from Sheffield University?

A. I graduated there with the degree of Bachelor of Philosophy.

Q. That was Sheffield Scientific School?

A. Yes sir, of Yale University.

Q. Have you studied bacteriology?

A. Yes sir. I first became interested in bacteriology when I first began to look after the executive work of the Medical School and in 1887 I imported a set of Koch's apparatus and established a laboratory there and followed the work in that laboratory for a number of years. Later, when bacteriology began to assume a considerable importance in water works, I began to do personal work and have for a number of years done bacteriological work as it relates to the practical work of water examination.

12667 Q. State, Doctor, whether or not you were one of the first to import and use bacteriological apparatus and methods in this country?

A. Yes sir. I believe that set that was imported at that time was among the earliest apparatus of Koch's that were imported in this country.

Q. State whether or not you have anything to do with bacteriology in your connection with the State Board of Health?

A. Yes sir, I make a number of bacteriological examinations of samples of water that are submitted for that purpose by the County officials principally.

Q. State whether or not you are a chemist and bacteriologist and familiar in a general way with the method and results of chemistry and bacteriology as applied to water and sewage?

A. I am.

Q. State, Doctor, whether or not you are familiar in a general way with the subject of rivers pollution?

A. Yes sir.

Q. And waters pollution as well?

A. Yes sir, I have had this brought to my attention partic-
ularly in the earlier part of my work, through the practi-
12668 cal work which was inaugurated by the State Board of
Health in Connecticut on the Rivers Pollution, and that
has continued up to the present time.

Q. State whether or not you are familiar with the various investigations that have been made, scientifically, bacteriologically and chemically speaking on the subject of Rivers Pollution?

A. In a general way, I am.

Q. Please state, Doctor, whether or not you have investigated epidemics of any kind?

A. Yes sir, I have been called upon through appointment in each case by the State Board of Health to investigate the number of epidemics which have occurred.

Q. Please state, Doctor, in a general way the various epidemics that you have investigated both for the State Board of Health of Connecticut and elsewhere?

A. An epidemic of typhoid fever in Waterbury, Conn.,

An epidemic of typhoid fever in Hartford,

An epidemic of typhoid fever in North Manchester,

An epidemic of typhoid fever in Stanford,

An epidemic of typhoid fever at Money Island Hotel in
12669 Branford, Conn.

One of typhoid fever in New Haven.

One of typhoid fever at the New Haven County Jail, in New Haven,

One of typhoid fever at Bristol.

One of typhoid fever at Forestville,
One of scarlet fever at Norwalk.
One of typhoid fever at Danbury.

Those are mentioned especially because they are epidemics on which I have made reports which have been published in each case.

Q. State, Doctor, whether or not you have been called in consultation with reference to other epidemics than those mentioned?

A. I have been quite frequently consulted in the way of small outbreaks, but the epidemics which have occurred in Connecticut, I have been sent to examine, for the most part. There was one in New Haven which was a milk epidemic in which I was in consultation, but which was investigated by the local authorities of the state, but I had nothing to do with it.

Q. What was the character of the epidemic at Hartford?

A. That was a typhoid fever epidemic which was traced 12570 to the pollution of the drinking water then being taken from the Connecticut River.

Q. What was the character of the epidemic at New Haven?

A. That was an epidemic of typhoid fever which was traced to the pollution of one of the supplies of drinking water of New Haven.

Q. What was the character of the epidemic at Forestville?

A. That was a typhoid epidemic which was traced to the pollution of the water supply which supplied that village through the taking into the pipes of water from a sewage polluted stream owing to a break in the main crossing the stream.

Q. State, Doctor, whether or not you have made these investigations as the Epidemiologist to the State Board of Health?

A. It has been the custom of the board to refer that sort of work to me, but they have never conferred that title upon me. I have made all the reports recently for the board in that line of work.

Q. Doctor, state whether or not you are acquainted with and have kept yourself informed of the various publications and literature upon typhoid epidemics throughout the 12671 United States?

A. I have read the reports of many such epidemics and meant to gather a general run of the character of them.

Q. Are you acquainted with the literature on the more important epidemics such as the one at Butler, Pa., Ithaca, N. Y., and Plymouth, Pennsylvania?

A. I am familiar with those outbreaks, the character of them.

ADJOURNED until 1:45 P. M. same day.

1:45 P. M., Tuesday, May 24, 1904.

12672 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

DR. HERBERT E. SMITH

resumed the stand for further direct examination by Mr. Jeffries, and testified as follows:

Q. Doctor, in addition to what was stated in your qualifications this morning, I will ask you whether or not you have recently been appointed to any position other than those which you mentioned this morning, in some institution?

A. About three years ago, I think it was, I was appointed as Lecturer on the Interpretation of Water Aanalysis in the Sheffield Scientific School of Yale University, and have continued to hold that position and to give instruction to the class in Sanitary Engineering in that branch.

Q. Doctor, I show you tables of mean results presented and read in evidence in this case by Professor L. P. Kinnicutt, and
ask you to examine that and state whether in your opin-
12673 ion a sanitarian and epidemiologist can from these tables
determine the condition of the Chicago Canal for sanitary purposes, which tables are known as tables A, B, C, D and E, table A consisting of analyses showing the changes which took place during the passage of the sewage of Chicago through the drainage canal, from Professor Jordan's analysis, from Ap 30th to June 25th, 1900, the same being the compilation of tables 119 to 123, contained in Streams Examination, which are the results of experiments made by Professor Jordan; table B representing the analyses showing the changes which took place during the passage of the sewage of Chicago through the drain-

age canal, based upon Professor Long's analyses, from June 5th to September 4th, 1900, compiled from tables 43 and 44 of the Illinois State Board of Health report of 1901; table C purporting to consist of analyses showing the changes which took place during the passage of the sewage of Chicago through the sanitary canal, according to Professor Palmer's analysis, from July 9 to October 5, 1900, taken from Palmer's tables 39 to 45 of Streams Examination; table D consisting of the mean of Long, Jordan and Palmer's analyses, compiled from tables 1, 2 and 3,
purporting to show the changes, parts removed and the
12674 per cent. of purification that took place during the passage
of the sewage of Chicago through the sanitary canal; table E representing the action of the septic tank on the removal of substances contained in sewage; all the tables contained in the book known as Streams Examination, Sanitary District of Chicago, having been introduced in evidence by the defendants and the report of the State Board of Health referred to by these tables having been submitted for identification.

Mr. Todd: I object to the question for the reason it is not competent for this witness to pass judgment upon whether Professor Kinnicutt could pass an opinion such as is asked in the question or not, but it is for the court to determine whether such an opinion carries weight with the court, and for the further reason that it is incompetent, irrelevant and immaterial, and is not rebuttal.

Also for the further reason that Professor Kinnicutt did not testify as an epidemiologist but strictly as a chemist and an expert on septic tanks.

A. I would state that the figures represented in these
12675 tables do not furnish sufficient data to permit me to form
a positive opinion as to the value, as a sanitary apparatus for the purification of the sewage of the drainage canal. The figures do show that there is a considerable solution of the suspended matter; that there is a considerable decomposition of the organic matter; that there is the development of a considerable amount of free ammonia.

These changes are such as are found taking place in sewage which is stored, by the agencies of the bacteria.

The tables also show that there is a considerable reduction

taking place in various ingredients in the sewage in passing through this canal. In so far there is a removal of the polluting material from the sewage, but in an important element in the discussion these tables are incompetent to form an opinion as to the destruction of the pathogenic organisms, particularly the typhoid fever, and there is no data with which I am acquainted which will give a true value to the extent to which bacteria may be destroyed or are destroyed in such an apparatus. The experiments which have been made tend to show that there is a reduction of the typhoid bacteria under such conditions, but
12676 how efficient such an apparatus is it, is impossible to state.

Mr. Todd: I move to strike out the answer for the reason that if the question is competent, the answer is not responsive, as this witness was not asked his opinion upon the tables, but was asked if any competent expert could express an opinion from the tables, and I move to strike it out for the same reasons in addition that are assigned as objections to the question.

Mr. Jeffries: Assuming, Doctor, that at all times during the analyses upon which these tables are based, there was nothing contained in the drainage canal except the concentrated sewage, state whether or not in your opinion these mean averages, as made up by Professor Kinnicutt, would not have shown a much greater reduction than they do show, owing to the fact that there is and was, at that time, 250,000 cubic feet of water per minute, from Lake Michigan, passing through the canal?

Mr. Todd: Object to the question for the reason it is not rebuttal and is therefore incompetent, irrelevant and im-
12677 material, and for the further reason that complainant introduced evidence upon the same subject in putting in their case in chief.

Mr. Jeffries: I suggest that this question is based upon the tables introduced by the respondents.

A. In my opinion the introduction of the large quantity of water discharged would tend to reduce the purification which would take place in an apparatus of this sort.

Mr. Jeffries: Q. What do you mean by the use of the word "apparatus" as used by you?

A. I mean the drainage canal.

Q. Now, Doctor, I show you tables 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, introduced and read in evidence by Professor Kinnicutt, these tables showing the mean of Professor Jordan's and Palmer's result, May to December, 1899, in the Illinois River, Joliet, North of Jackson Street; Ottawa, La Salle, Henry, Averyville, Pekin, Havana, Beardstown, Kampsville and Grafton. I will ask you to state what conclusions you draw from these tables, and what these tables of mean results show with reference to the condition of the stream at these points, as to its average pollution, at all times of the year?

12678 Mr. Todd: Object to the question upon the ground it is not rebuttal and is not impeachment, and has no foundation laid for the impeachment of Professor Kinnicutt in the cross-examination conducted by the complainant and therefore not being rebuttal or impeachment it is immaterial, incompetent and irrelevant, as all the questions arising out of the purification or impurification of the Illinois River from the mouth of the Chicago River to Grafton is a matter that has been introduced in evidence in chief by complainants in their original case, and the evidence would be purely accumulative and is therefore incompetent, irrelevant and immaterial.

Mr. Jeffries: There is no effort made to impeach Professor Kinnicutt, but this question is directed to the competency of the tables, for the reason it fails to show true conditions at all times of the year.

Personally, will say that failure to cross examine Professor Kinnicutt is not brought about by any such derilection of duty on my part, I being detained in the trial of a case at that time, not being desirious of interfering with the progress of this hearing, and to not discommode or inconvenience respondents'

12679 counsel who had treated us so fairly and agreeably that I permitted Professor Kinnicutt to leave the stand without cross examination.

Mr. Todd: Accepting what counsel has said in the matter does not change the rules of evidence in this case and make an exception to a well established rule such as I believe I have enunciated in my objection.

Mr. Jeffries: I know of no rule of law which prohibits opposing counsel to attack the incredibility of a table or the competency of a table simply because the person who drafts the table was not cross-examined in reference to it.

Mr. Todd: Counsel for defendants make no such contention that there is such a rule, but contends that where complainant has gone into the whole question in chief he can not on re-direct examination go into the question as being proper rebuttal.

Q. Question read.

A. These results show the average composition of the samples of water at the times and places at which they were collected. The several samples show that in the upper portion
12680 of the water way there was a very high chemical and bacterial pollution; that there was a gradual diminution in the amounts of the various chemical constituents in the progress down the river and that there were certain places where there was an increase in these constituents; the figures for the samples taken at Grafton show that there was in those samples a very considerable evidence of sewage contamination still remaining. There was some variation in this diagram, also in bacteria, the number at the Grafton station being somewhat higher than at the Kampsville station, for instance.

The tables fail to show the true conditions of the river at these several stations at all times because a sample taken from a running stream, from time to time, can not of course show the composition of the river at that place at other times, and further, there is no evidence in these tables that the samples taken at the time they were taken were proportional to the flow in the river, and obviously they would represent a different proportion of the constitutents in the river at times of flood from what they would at the time of low water, the samples being of the same size.

12681 MR. TODD: I move to strike out the answer for the reason given in the objection to the question, and for the additional reason that no witness has testified that the samples taken, as evidenced by the tables, express true conditions for the entire year, but only for conditions for the time covered, the period covered during the taking of the samples, and for the additional reasons given in my objection to the question itself.

MR. JEFFRIES:. Q. I show you tables 57 to 64, inclusive, Doctor, introduced in evidence by Professor Kinnicutt, and based upon the mean of Jordan and Palmer's results, from January to June, 1900, and the following points in the Illinois River: Table 53, Joliet; table 54, Morris; table 55, Ottawa; table 56, La Salle; table 57, Henry; table 58, Averyville; table 59, Wesley City; table 60, Pekin; table 61, Havana; table 62, Beardstown; table 63, Kampsville, and table 64 at Grafton, and ask you to examine these tables and state whether or not from the mean results shown by them positive conclusions can be drawn as to the sanitary condition of the water in the river at those points at all times in the year?

MR. TODD: Object to the question for the same reasons
12682 given in my objection to the previous question.

A. In my opinion these tables do not show the condition of the water in the river at the several points at all times of the year for the reason that the samples were taken occasionally and not continuously; that they did not as far the tables show, take into consideration the flow at the time the samples were taken and that in general an average of this sort can not show the condition of the stream at other times than those at which the samples were taken.

MR. TODD: I move to strike out the answer for the same reasons given in my motion to strike out the previous answer.

MR. JEFFRIES: Q. Doctor, I will show you tables 1 to 12, inclusive, introduced in evidence by Professor Kinnicutt, as giving the mean of Doctors Long and Palmer's results for May, June, July and August, 1899, and 13 to 24, inclusive, the mean of Doctors Long and Palmer's results for May, June, July and August, 1900, and will ask you to state what, in your opinion, is the value of these tables as to their showing the sanitary condition of the water in the Illinois River at all times
12683 of the year?

MR. TODD: Object to the question for the same reasons heretofore stated in my objection to the previous question.

A. In my opinion these tables fail to show the condition of the water in the river at all times and seasons for similar reasons stated in my answer to your last question.

MR. TODD: I move to strike out the answer for the same reasons advanced in my previous motion.

MR. JEFFRIES: Q. Doctor, have you examined the individual results upon which these averages were based?

A. I have.

Q. State whether or not you have noticed any individual samples, the determination of which deviate markedly from the average in the evidence of sewage pollution?

MR. TODD: Object to the question for the same reasons heretofore stated.

A. In my examination of the individual results upon which these tables of averages are based, I have noted many results which deviate widely from the average.

As an illustration, on table 101 in the Streams Examination, which relates to the analysis of the Illinois River at Grafton during 1899, I find that on November 8th, the samples
12684 showed a chlorine of 4 parts per million; on May 31st
of 3.7 parts per million, while the average given in Professor Kinnicutt's table of the results obtained at this point is 18.4 parts per million.

I would say that on that particular table there were 17 samples, more than half, therefore, that were above the average in chlorine, and there were 16 that were below the average.

With regard to the free ammonia, I find that on December 6th there was present 1.12 parts per million, and on June 21st, .04 parts per million, while the average of all the determinations at that point gave 0.23. There were 12 samples above the average and 21 samples below the average.

In the same tables, the figures for suspended matter, or suspended residue referred to in another place as suspended solids, was, on May 31st, 873.8 parts per million, and on October 11th was 1 part per million, while the average of all the determinations is given as 82.4.

These indicate some of the ranges which I have noted, and similar discrepancies are found in the other tables.

12685 MR. TODD: I move to strike out the answer for the same reasons heretofore given.

MR. JEFFRIES: Q. Doctor, state whether or not and in what way, if any, true conditions fail to be displayed from the tables of averages such as these about which we have been testifying?

MR. TODD: Object to the question for the same reasons.

A. The general average does not show a true condition because the general average can only relate to the conditions at the times and places when and where the samples were taken.

In a stream of running water, which varies in volume, it is very important that the samples should be taken in such volume as will indicate the relative flow at the time the samples are taken.

For another reason a sewage contaminated stream varies greatly from time to time in its content of impurity, depending largely upon the irregularities in the discharge of the sewage, at one time the sewage being of a certain character and at another time differing widely from it, either because of the sort of discharge of materials from factories or manufacturing establishments or something of that sort, or from the varia-
12686 tions which are found in the flow of sewage in the matter from houses at or during different hours of the day.

Moreover, there is a very marked difference in the flow of streams, due to the variable rainfall at different seasons and times. This has the effect not only of increasing the volume of the flow, diluting it at one time, the constituents over the conditions which prevail at another time, but the larger flow tends to bring down the stream accumulated materials and form movable deposits, both upon the watershed and in the stream itself. For these various reasons an average result can not show the condition of the stream at all times.

Mr. Todd: I move to strike out the answer for the same reasons heretofore stated.

Mr. Jeffries: Q. Doctor, in the present developed state of sanitary science, state whether or not a table of averages, such as were introduced by Professor Kinnicutt, are considered by the scientists as sufficient to enable one to make a competent determination of the sanitary condition of water in a running stream?

12687 Mr. Todd: I object to the question for it is not competent for this witness to answer a question comprehending the entire learning on sanitary science, to pass judgment upon the ability of others to express an opinion in regard to sanitary problems, and for the further reason that the question is not rebuttal to any testimony introduced in this case, and the question of averages, of chemical as well as bacterial examinations have been introduced and sustained by the witnesses who testified in this case for the complainant, and it is not competent to contradict complainant's own witnesses upon a proposition plainly embodied in the question, and it is therefore incompetent, irrelevant and immaterial.

Mr. Jeffries: Counsel is mistaken in the purpose of the question. It is only to show the weight of credibility that must be attached to the particular tables here referred to and introduced in evidence by Professor Kinnicutt.

Mr. Todd: In reply, counsel is aware of its purpose, but he objects to its effect.

A. In my opinion the tables of averages which are re-
12688 ferred to as having been introduced by Professor Kinni-
cutt do not form a competent basis in the present condition of sanitary science to permit a definite opinion as to the sanitary condition of the stream to which they relate.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection.

Mr. Jeffries: Q. Upon what do you base your last answer?

Mr. Todd: Object to the question as incompetent, irrelevant and immaterial.

A. I base my answer first upon the reasons already assigned why a general average can not be taken as representing the general character of the stream to which they relate at all times.

And further, I base my opinion upon my belief that chemical analyses do not and can not show all the evidences of dangerous pollution which may exist in a stream. The chemical analysis is addressed to the deduction and determination of certain
elements which are useful in determining the presence or
12689 not of sewage in a stream, but in the present state of the
science it is impossible to decide whether certain results are or are not evidence of sewage contamination and further, that there are certain ingredients which may be present in a stream coming from sewage and which are of material importance which are not revealed at all by the chemical analysis. In

my opinion, therefore, the chemical analysis alone is not a sufficient basis to decide whether a sewage polluted stream contains the dangerous elements of sewage.

Further, I base my opinion upon my belief that in the present state of sanitary science the bacteriological analysis does not reveal in all cases the presence of those constituents of sewage which are dangerous.

And, further, I would state that in the present condition of sanitary science, neither the chemical nor the bacteriological analysis alone, nor both together, can be absolutely relied upon to show the presence in a stream of those substances which may come from sewage and do come from sewage and which are dangerous.

Mr. Todd: I move to strike out the answer for the reason 12690 that it is not rebuttal of any testimony introduced in evidence by the defendants, but is a contradiction of the testimony introduced in evidence by the complainants, to wit: the testimony of Doctor Ravold and especially Dr. Teichmann and Professor Keiser, and is therefore incompetent, irrelevant and immaterial and is not proper at this stage of the case.

Mr. Jeffries: Q. Doctor, you have examined the book known as Streams Examination, all the tables from which were introduced in evidence in this case, have you?

A. I have.

Q. In giving your answer to the last questions have you considered the tables contained in this book known as Streams Examination, and what you have learned from it?

Mr. Todd: I object to the question for the same reason.

A. In answering your questions relating to the analysis I have taken into consideration the information which I obtained by consideration of the tables in the book known as Streams Examination.

Mr. Jeffries: Q. From your examination of all the tables contained in this book known as Streams Examination, 12691 and which said tables have been introduced in evidence, and from the tables introduced in evidence by Professor Kinnicutt state whether or not you are able to say that all the harmful elements and disease producing bacteria discharged into the canal at Chicago have become eliminated from the Illinois River by the time that it reaches Grafton?

Mr. Todd: Object to the question for the same reasons heretofore stated.

A. From my examination of the results given in the tables in the book, Streams Examination, and of the tables of averages based thereon, I would say that I am unable to state that they show that all injurious ingredients have been eliminated from the sewage.

Mr. Todd: I move to strike out the answer for the same reasons.

Mr. Jeffries: Q. Are you acquainted with the extent of the population residing upon the watershed of the Illinois River the rural and the urban population?

A. I have seen the figures, yes sir.

12692 Q. Have you acquainted yourself, Doctor, with the relative amount of sewage that is immediately discharged into the Illinois River for the various periods mentioned, upon the Desplaines and upon the banks of its tributaries, exclusive of the Sanitary District of Chicago?

Mr. Todd: Objected to as incompetent, irrelevant and immaterial.

A. I have examined the figures showing the amount of sewage discharged into the Illinois River at various points upon its course.

Mr. Jeffries: Q. Doctor, have you made yourself acquainted with the velocity flow of the Illinois River from Chicago to the Mississippi?

A. I have examined figures showing the flow of the Illinois River at the points mentioned.

Q. The figures that you examined in reference to that were those determined by Professor Van Ornum and Isham Randolph are they not?

A. I understood that they were the figures introduced by 12693 the gentlemen named.

Q. Taking into consideration, Doctor, the extent of the urban population residing upon the water shed of the Illinois River, exclusive of the city of Chicago, and taking into consideration the usual volume of water passing down that river, together with the added volume of 250,000 cubic feet per minute, from Chicago, state whether or not in your opinion the chemical and bacterial results shown upon the tables contained in Streams Examination and the results upon the tables introduced in evidence by Professor Kinnicutt show the sanitary chemical and bacterial condition of the water in the Illinois River to be higher or lower from a sanitary standpoint than ordinarily exists in rivers of this kind having similar population and flowing similar volumes of water?

Mr. Todd: Object to the question for the reason it is not rebuttal and for the additional reason that this whole question was gone into in chief by the complainant, and it is therefore incompetent, irrelevant and immaterial.

Mr. Jeffries: I suggest it goes to the competency of the 12694 tables introduced and the conclusions drawn therefrom.

A. Taking into consideration the urban population upon the several water sheds tributary to the Illinois River, exclusive of that of the Chicago Sanitary District, I will state it is my opinion that the results shown in the tables in the examination of streams and in the tables of averages based upon them, show that at the times when these samples were taken there was more evidence of sewage than I should expect in a river of this size and population.

Mr. Todd: I move to strike out the answer for the same reasons.

Mr. Jeffries: State whether or not in your opinion, Doctor, the chemical and bacterial data found in the tables contained in Streams Examination, and the tables introduced in evidence by Professor Kinnicutt, show more or less any such bacterial and chemical constituents which are usually considered as evidence of sewage than which you would expect in event the sewage from the sanitary district of Chicago was not discharged into that river, the same volume of water flowing down the river in 12695 each event?

Mr. Todd: Object to the question for the same reasons stated in my previous objection.

A. In my opinion the tables referred to do show that there was at the times when the samples were taken more evidence of sewage contamination than I should expect to find from the urban population on the watersheds tributary to the Illinois River, exclusive of the Chicago Sanitary District.

Mr. Jefferies: Q. Assume, Professor, that a larger portion of the sewage of Chicago passed through the old Illinois and Michigan Canal in a more concentrated condition than it does through the drainage canal; assuming further that during the greater part of the year, under such conditions the water in the Illinois River, practically from Grafton to Henry, was covered with a green scum as though in a quiescent condition, and as described by some of the fishermen on the river, who testified for respondent, stood in a stagnant condition with no perceivable current, such that when a skiff would be rowed across it, it would separate the green scum and leave the line of separation
distinct and visible for a great distance behind; that if a
12696 chunk should be thrown in the river it was as liable to float
up stream as down stream, depending altogether upon the direction of the wind; that the five dams practically retarded the progress of the water down the stream; that in order to protect navigation it was necessary for them to erect banks on top of the dam so as to increase the height of the water above the dam; assuming further that since the opening of the canal that there has been a continuous current at all times of the year, both above, below and over the respective dams. State whether or not upon these assumptions the facilities for removal of the pathogenic bacteria and harmful ingredients of the water coming from the sewage of Chicago were not better prior to the opening of the drainage canal than subsequent to that time, and also is it not a fact that such facilities for removal are not and can not be displayed by the table of averages and by the tables themselves contained in Streams Examinations and introduced by Professor Kinnicutt and which you have examined,
the volume of water that passed through the Illinois and
12697 Michigan canal prior to the opening of the drainage canal
ranging from 19,000 to 49,000 cubic feet per minute, and the volume of water passing through the drainage canal since its opening ranging from 200,000 to 250,000 cubic feet per minute?

Mr. Todd: Object to the question for the reason that the whole substance of the question has been gone into as part of complainant's original case as well as the second question contained in the preceding question, and it is therefore not rebuttal testimony and consequently is incompetent, irrelevant and immaterial.

Mr. Jeffries: I suggest in response to what Counsel has said that the question is perfectly competent, and is based solely upon evidence introduced by the respondents, both as to the tables and as to the condition of the water of the Illinois River both prior and subsequent to the opening of the canal, as testified to by the fishermen and others living upon that stream.

Mr. Todd: In reply Counsel will state that on a careful reading of complainant's case by the court, it will be evident that this question is not rebuttal. 12698

A. In answering your question I have taken into consideration the assumptions and statements made and would state it as my opinion that the conditions assumed and stated to be present in the river prior to the opening of the drainage canal were such as would afford greater facilities for the removal of pathogenic organisms than those conditions which exist since the opening of that canal.

And, further, I would state as my opinion that the data furnished by the tables in the book of Streams Examintion, and the tables based thereon, do not furnish data for determining the extent to which these pathogenic organisms have been removed.

Mr. Todd: I move to strike out the answer as it is evident from the answer itself that it is not rebuttal but the original case of complainants and therefore incompetent, irrelevant and immaterial and not proper evidence.

Mr. Jeffries: Q. Doctor, have you examined the typhoid mortality statistics introduced in evidence in this case, showing the number of deaths from typhoid that have occurred in the principal towns and cities upon the water shed of the Illinois and Mississippi and the Missouri within the last six or seven years? 12699

A. I have.

Q. Are you acquainted with the typhoid statistics of the city of Chicago?

A. I am.

Q. Are you acquainted with the extent of the population of the drainage district of Chicago?

A. I am.

Q. Have you informed yourself with reference to the physical character and condition of the Illinois River?

A. In a general way, by description.

Q. State whether or not you are acquainted with the character of the river bed of the Illinois River?

A. I am.

Q. Speaking as a sanitary chemist, familiar with the pollution of rivers, and chemical analysis as a means of determining the character, and after examination of the tables introduced in evidence by Professor Kinnicutt, please state whether or not it is in your opinion possible to determine from such chemical and bacteriological data whether the sewage of Chicago
12700 has or has not at all times and at all seasons of the year become purified before reaching Grafton?

Mr. Todd: I object to the questions for the reasons heretofore stated.

A. In my opinion the data furnished in the tables show that there has been considerable removal of the polluting material introduced into the river from the sewage of Chicago, but that they are not sufficient to determine that the purification from the dangerous elements in the sewage has been complete at all times and all seasons.

Mr. Todd: I move to strike out the answer for the reasons heretofore given.

Mr. Jeffries: Q. Speaking as an expert in the interpretation of sanitary water analysis, bacterial analysis and all other means of determining the sanitary condition of a running stream I will ask you to state your opinion concerning the purification of the sewage of Chicago at the time it passes out of the drainage canal.

Mr. Todd: Object to the question for the reasons heretofore stated, namely that it is not rebuttal.

12701 A. Basing my opinion upon the results of the chemical and bacteriological analysis which have been furnished, and the tables referred to, and upon other data within my knowledge bearing upon the subject I would state it as my opinion that the sewage is not purified from the harmful agents at the time it is discharged from the drainage canal.

Mr. Todd: I move to strike out the answer for the reason that it is not rebuttal and it not contradictory of any testimony given in this case by any witness that has heretofore testified.

Mr. Jeffries: Q. Assuming that the water passes from the city of Chicago through the canal into the Des Plaines River, and down the Illinois to the Mississippi, past the chain of rocks at St. Louis, within from ten to twenty days, state your opinion as an expert on water supply for cities and towns as to whether or not the waters of the Mississippi River at the chain of rocks are less available for drinking purposes and more liable to contain water borne diseases such as typhoid now than it did before the sewage of the Sanitary District from Chicago was borne into the drainage canal and through it to the Illinois River?

12702 Mr. Todd: Object to the question for the reason that the identical question was asked of Professor Sedgwick, Professor Fuller and all the other epidemiologists, witnesses, who testified in this case in chief on the part of the complainant, and it is therefore plainly not rebuttal but a part of complainant's original case and is therefore incompetent, irrelevant and immaterial.

A. I will state it as my opinion, based upon the facts which you have stated that the water at the chain of rocks is less available for sanitary use than it was before the opening of the sanitary canal, and that there is a very much greater liability of the infection with typhoid bacilli of persons drawing water from that point in the river.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Doctor, Professor Kinnicutt in his direct examination by counsel for respondents was asked this question,
and I desire to ask it of you: If an increased volume of
12703 water in the Illinois River, by the addition of the water
of the drainage canal at the rate of 250,000 cubic feet per minute would make an increased speed in the current of the Illinois River, would that increase in said current have any effect in increasing or diminishing the liability to typhoid and other water borne diseases on the part of the inhabitants of the State

of Missouri using the water of the Mississippi River for drinking purposes below the mouth of the Illinois?

Mr. Todd: Object to the question for the reason that the question asked was a question put to Professor Sedgwick by counsel for complainant and that the question put to Professor Kinnicutt was put by way of rebuttal, and it is not competent to ask this witness a question which was gone into in chief by complainant under the assumption that the question originated in the direct examination of Professor Kinnicutt, when as a matter of fact the question was framed and asked by the counsel who is now asking it, and it is therefore incompetent, irrelevant and immaterial and not proper rebuttal.

Q. Question read.

A. In my opinion an increase in the flow of the Illinois River as assumed would very largely increase the liability 12704 of the infection of persons drawing a water supply consisting in whole or part of water from the Illinois River.

Mr. Todd: Move to strike out the answer for the reason given in my objection to the question.

Mr. Jeffries: Q. Doctor, in his testimony Professor Kinnicutt was asked this question by counsel for respondent: "Based upon your knowledge as a chemist, bacteriologist and sanitarian, is there anything that you know of that would lead you to believe that the water coming from the Illinois River was infected by the sewage from Chicago, and assuming that the water of the Illinois River, mixed with the waters of the Mississippi at Grafton, and of the waters of the Missouri above the intake and the waters of the Illinois and Missouri Rivers thus comingling with the waters of the Mississippi, state whether or not you then consider the waters of the Mississippi River a menace to the inhabitants of the State of Missouri living on its banks below the mouth of the Illinois River?"

Mr. Todd: Object to the question for the same reasons 12705 advanced in my objection to the last question and for the additional reason that because a question was asked of defendant's witness, that simple fact does not make it competent to ask in rebuttal, in view of the fact that the subject matter of the question as well as the question itself is part of the original case of complanants and is not rebuttal of anything offered in evidence by the defendants and is therefore incompetent, irrelevant and immaterial.

A. Replying to your question, I will state that there are factors in my knowledge which would lead me to believe that the Illinois River was infected by the sewage of Chicago, and that the mingling of this water with that of the Mississippi River and Missouri River is a serious menace to the health of persons living below the mouth of the Illinois River.

Mr. Todd: I move to strike out the answer for the reasons given in the objection.

12706 Mr. Jeffries: Q. Doctor, taking into consideration all of the chemical and bacterial data found in the tables contained in Streams Examination, which tables have been introduced in evidence by the respondents, and the tables introduced in evidence by Professor Kinnicutt, and assuming that there is no typhoid fever pollution of the waters upon the water shed of the Mississippi River and its tributaries above the intake of the St. Louis water water works other than that derived from the sanitary district of Chicago, do you or do you not believe that typhoid fever germs from said district of Chicago are liable to find their way into the water supply of the city of St. Louis through the intake of the waterworks of the city of St. Louis at the chain of rocks?

Mr. Todd: Object to the question on the ground it is not rebuttal; that this whole question was gone into in chief by complainant and it is not proper to reopen the case after complainant has rested, and it is therefore not rebuttal and is incompetent, irrelevant and immaterial.

12707 A. Replying to your question, and taking into consideration the statements made in it, I will state it as my opinion that I do believe that typhoid bacilli from the sewage of Chicago are liable to find their way into the water supply of the city of St. Louis through the intake at the chain of rocks.

Mr. Todd: I move to strike out the answer for the reason given in the objection to the question.

Mr. Jeffries: Q. Doctor, based upon the chemical and bacterial data contained in the tables found in Streams Examination, which have been introduced in evidence, and the tables introduced in evidence by Professor Kinnicutt, and taking into consideration all the knowledge which you possess upon the subject of sanitary science, do you or do you not consider that the Illinois River water containing mixed sewage and canal water from the Chicago Drainage Canal has rendered less safe and wholesome than before the opening of the canal, the waters of the Mississippi River for drinking purposes on the part of the inhabitants of the State of Missouri below St. Louis and

12708 below Grafton, and the inhabitants of the city of St. Louis?

Mr. Todd: I object to the question because it is not proper rebuttal and for the other reasons stated in my previous objection, and it is incompetent, irrelevant and immaterial.

A. Taking into consideration the statements made in your questions, I will state it as my opinion that I would believe that the introduction of the sewage from the City of Chicago has rendered the water of the Mississippi River less wholesome as supply of drinking water.

Mr. Todd: I move to strike out the answer for the same reasons as contained in my objection to the question.

Mr. Jeffries: Q. Doctor, please state in a general way as a sanitarian and epidemiologist what is necessary in order to enable one to pass intelligent judgment upon the sanitary character of water?

Mr. Todd: Object to the question as not rebuttal.

12709 A. To form a competent opinion as to the sanitary condition of a water and its suitability for use and as a supply of drinking water, one should avail himself of all knowledge obtainable on the subject. A chemical examination may give such results as would indicate that the water is sewage polluted. The discovery of such evidence must always make such a water to be regarded with suspicion. To decide the importance of the suspicion one must determine the condition and the extent as far as possible from other means as to the extent and nature of the pollution.

There are cases, however, which the chemical analysis will fail to give positive data as to the presence of sewage even when it is undoubtedly present as shown by other data.

Regarding the bacteriological analysis, I would say that

it is frequently possible to obtain results which also indicate the presence of sewage contamination and that such evidence must always render that water suspicious, and that the import-
ance of the suspicion must be determined by a thorough
12710 examination as to the source and nature of the source of
the pollution, but there are cases in which the results of the bacteriological analysis will not disclose the presence of the ingredients of sewage when it is known by other tests that they are present.

Indeed, the bacteriological tests have frequently failed to show the evidence of sewage contamination positive in streams which were known to have received sewage contamination. When one must depend upon such data for the determination of the suitability of a proposed water supply, one must use not only the evidence of the chemical and bacteriological examinations but all data relating to the surroundings of the source from which the water comes.

In determining, however, whether a water in use has been a subject of sewage pollution, unquestionably the most positive way of obtaining evidence is a careful study of the effects which have been produced by the water upon the persons who have used it. Where a large community uses a water which has been
sewage polluted and the injurious ingredients of the sew-
12711 age still exist in the water it is inevitably shown in its
results upon the health of the people. This is so much the case that the statistics of typhoid fever in a community is on the whole the best evidence which pertains to the fact of sewage pollution.

I would state, therefore, that in my opinion the best test which can be applied to decide whether a given water supply has been infected by sewage is to study the typhoid statistics of the community using the water.

Mr. Todd: I move to strike out the answer for the reasons given in my objection to the question.

Mr. Jeffries: Q. As sanitary expert, availing yourself of all the chemical and bacterial knowledge which is available to you, what is your opinion as to whether typhoid bacilli living in the sediment of a polluted stream for the period of sixty days would be able to produce typhoid fever if taken into the human system?

Mr. Todd: I object to the question for the reason the same question was asked of Professor Sedgwick on re-direct 12712 examination as well as the other witnesses for the complainant and it is a part of complainant's original case and is therefore not rebuttal of anything that has been introduced in evidence on the part of the defendants in this case, and is therefore incompetent, irrelevant and immaterial.

A. I would state it very positively as my opinion that typhoid bacilli living in the sediment of a polluted stream for the period of sixty days would be able to produce typhoid fever if taken into the human system.

Mr. Todd: I move to strike out the answer for the reasons given in my objection to the question as not rebuttal and part of complaintant's original case.

Mr. Jeffries: Q. What is your opinion as a sanitary expert as to whether pollution and typhoid fever bacilli coming from the sewers of Chicago, through the drainage canal, deposited in the bottom of the Des Plaines and Illinois Rivers can remain there for the period of from thirty to sixty days and yet retain their dangerous qualities as well as pathogenicity?

12713 Mr. Todd: Object to the question for the same reason as given to the last question.

A. I will state it as my opinion that I believe when typhoid bacilli are deposited on the bottom of the Des Plaines or Illinois River, between Chicago and Peoria for a period of thirty or forty days they might retain their dangerous qualities as well as their pathogenicity, for I know of nothing which would make it certain that such an organism would meet with any material which would be certainly destructive to it under such conditions.

Mr. Todd: I move to strike out the answer for the same reason as made in my objection to the question.

Mr. Jeffries: Q. From your knowledge of the Illinois River and your knowledge as a sanitary expert, together with the chemical and bacterial knowledge derived from the tables contained in the book known as Streams Examination and which have been introduced in evidence by the respondent, what your opinion as to whether the sewage from the city of Chicago,

passing through the drainage canal into the Illinois River
12714 at different seasons of the year and at different stages of
the water in this river would be a danger and a menace to
the inhabitants of Missouri and St. Louis using the water of the
Mississippi at the intake tower at the chain of rocks for drinking purposes?

Mr. Todd: Object to the question for the same reasons heretofore stated in my objection to previous questions of the same character and kind.

A. I would state it as my opinion that sewage from the city of Chicago, passing through the course described in the question would be a menace and a danger to the inhabitants of Missouri and St. Louis using the water of the Mississippi River at the intake at the chain of rocks, for I know of nothing with which the infection contained in such sewage would meet which would be certainly destructive of it, and from my knowledge of conditions at Chicago such sewage must be very largely at times infected with typhoid bacilli.

Mr. Todd: Move to strike out the answer for the same reasons given in my objection to the question.

12715 Mr. Jeffries: Q. Based upon the chemical and bacterial
data contained in the tables in Streams Examination and introduced in evidence by respondents, and based upon all the knowledge which you possess as a sanitarian, chemist and bacteriologist, I will ask you to state whether or not in your opinion harmful elements of the sewage of the Chicago River reach the intake tower of the St. Louis water works at the chain of rocks?

Mr. Todd: Object to the question for the reason it is not rebuttal and the whole question was gone into in chief by complaintant, and it does not make it rebuttal by asking the witness's opinion, based upon the tables introduced, together with all other knowledge which he has upon the subject, and therefore it is incompetent, irrelevant and immaterial.

Mr. Jeffries: I suggest that at the time the evidence on the part of the complainant was introduced we had no knowledge of the tables contained in Streams Examination and we certainly have the right to introduce the opinion of witnesses as to the
effect of and the results contained in those tables so in-
12716 troduced by the defendants.

Mr. Todd: Counsel's suggestion does not remedy the effect of the question.

Mr. Jeffries: And have the right to controvert the opinions of respondent's witnesses based upon those tables.

Mr. Todd: Counsel's statement does not remedy the objection as the question is plainly not rebuttal but a part of complainant's original case.

A. Taking into consideration all the knowledge which I have bearing upon your question, I will state it as my opinion that harmful elements of the sewage of Chicago have reached the intake of the St. Louis water works at the chain of rocks and have been the cause of typhoid fever among the persons using that water.

Mr. Todd: I move to strike out the answer for the reasons assigned in my objections.

Mr. Jeffries: Q. Taking into consideration, Doctor, the contents of the tables contained in Streams Examination, which have been introduced in evidence, and the contents of the 12717 tables introduced in evidence by Professor Kinnicutt, and taking into consideration all the knowledge that you possess in regard to the chemical, bacterial and physical condition of the water in the Illinois River, and the different towns sewering into the Illinois River and its tributaries, and the population upon the Illinois River water shed, both rural and urban, the stages of the river in all conditions during all the seasons of the year, what is your opinicn as a sanitarian as to the effect of the flow of the sewage of Chicago through the drainage canal into the Des Plaines and Illinois Rivers, upon the inhabitants of the State of Missouri and the citizens of the city of St. Louis using the water of the Mississippi River for domestic purposes?

Mr. Todd: I object to the question for the same reasons heretofore stated.

A. Taking into consideration all the data which you have enumerated in your question, I would state it as my opinion that the flow of the sewage of Chicago from the sanitary 12718 or drainage canal, through the Illinois River, has had a deleterious effect upon the health of the persons living in St. Louis and using the water drawn from the intake at the chain of rocks.

Mr. Todd: I move to strike out the answer for the reasons given in my objection to the question.

Mr. Jeffries: Q. From the studies that you have made upon the question of self purification of running streams, I will ask you to state what is your opinion as to the ability of a running stream to purify itself so as to be free from all pathogenic bacteria that may be discharged therein at a given point so that the zone of purification may be determined to exist at a certain point, and that this given point may apply under all conditions, local and otherwise, at all velocities and volumes of water, all temperatures of weather and seasons of the year?

Mr. Todd: I object to the question on the ground and for the reason that the same question was gone into in complainant's original case and is not rebuttal and is therefore incompetent, irrelevant and immaterial.

A. The conditions affecting the purification of streams
12719 from the materials introduced by sewage are so complex
that in my opinion it would be impossible by the ordinary methods to determine at what point in the river the purification was always effected, the only way which I can suggest as being entirely satisfactory for the solution of such a problem is the study of the results of the use of such a water by a considerable community. If these fail to show any evidence of a deleterious effect produced by the water, and especially if they fail to show any evidence of typhoid fever, that typhoid fever has been produced by the use of the water, I should think we might reasonably conclude that that point was without the zone of danger during the time of the experiment, but owing to the fact that the chief deleterious constituents of sewage are living organisms, that they may be protected at certain times and in certain numbers by being enveloped in solid materials which would protect them from the influences ordinarily working against them in
streams, it would be impossible to predict with certainty
12720 that at some other time than the time of the experiment
the water would be perfectly safe at that point.

It is important to recognize in the question of sewage pollution that the chief injurious ingredients are living organisms and the question of dilution does not come into the discussion to anything like the extent that would be the case if the injurious ingredients were inert chemical substances.

If this were the case it is perfectly certain that we could reach a point where the most harmful chemical substances could be diluted to such a point that the dose in any given amount of water in the stream would be without effect upon the living persons, but with regard to a living organism we have to recognize the point that the dilution does not effect the individual organism but only its dissemination through the water, and that therefore it is possible to find in one portion of the water something that would be deleterious while in other adjacent units of the same size there might not be any.

Mr. Todd: I move to strike out the answer for the reasons given in my objection to the question.

12721 Mr. Jeffries: Q. Doctor, Professor E. G. Smith in his testimony on behalf of defendant was asked this question, "What do you say as to the assumption that typhoid germs could pass from the sewers of Chicago by way of the drainage canal to Lake Peoria and be deposited in the bed of Lake Peoria for the period of a month, as to whether or not the typhoid germs coming from the drainage canal under conditions as they exist, could live for the period of a month and not be destroyed at the end of that period?" said "In regard to the assumption that typhoid germs could pass from the sewers of Chicago by way of the drainage canal to Lake Peoria and be deposited there in the bed of Lake Peoria for a period of a month, it is my opinion from my study in regard to the purification of the stream embracing any knowledge upon the analytical data submitted as evidence in this case, which data indicates the removel of sewagic bacteria before Lake Peoria is reached, it would follow that the typhoid germs from the city of Chicago and the drainage canal did not reach as far down as Peoria, and in further support of this view we have a great deal of evidence secured by the results of experiments upon the duration of life of the typhoid fever
12722 germ showing that in the water of the Illinois River it does not live for a period of more than three or four days." I will ask you to state whether or not in your opinion typhoid fever germs deposited in the waters of the drainage canal at Chicago and carried thence into the Illinois River by

way of the Des Plaines River do or do not live for a period longer than from three to four days?

MR. TODD: I object to the question on the ground it is not rebuttal as the longevity of the typhoid bacillus was gone into in chief by the witnesses for the complainant and the question which is asked of Professor Smith was one of the questions asked by the counsel for the state of Missouri of George W. Fuller when he was a witness on the stand in this case, and it is therefore, incompetent, irrelevant and immaterial.

A. Replying to the question I would say that I know of no experiments which are entirely satisfactory as proving typhoid bacilli are not able to survive the immersing in sewage for a period of three or four days; that there is nothing in the way of experimental knowledge to show that the typhoid bacilli 12723 may not survive in sewage for longer periods, and that taking these facts into consideration, and the further fact that typhoid bacilli might be deposited in the bottom of a stream at any point between the emptying of the drainage canal and the mouth of the Illinois River under conditions which would protect it from such deleterious influences as the sewage exerted upon the bacteria in the experiments which are referred to, especially in the question which you asked, it would be my opinion that typhoid bacilli might survive a very much longer period than three or four days and even be likely to do so if they were deposited upon the bottom of the Illinois River.

Mr. Todd: Move to strike out the answer for the reason given in my objection to the question.

ADJOURNED until 8:00 p. m.

12724 Room 282 Southern Hotel, St. Louis, Mo. 8:00 p. m., Tuesday, May 24, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

DR. HERBERT E. SMITH

resumed the stand for further direct examination by Mr. Jeffries, and testified as follows:

Q. Doctor, state whether or not you have examined the evidence introduced by Doctors Zeit, Jordan and Russell with reference to certain experiments conducted by the use of parchment sacs for the purpose of determining the longevity of typhoid bacilli in the waters of the canal and the Illinois River so as to exemplify true conditions in that water?

A. I have.

Q. Have you familiarized yourself with that testimony in this connection?

A. In a general way I have.

12725 Q. State, Doctor, whether or not in your opinion these experiments so conducted by Doctors Zeit, Jordan and Russell exemplify actual conditions existing in the running waters of the canal and the Illinois River with reference to the longevity of the typhoid bacilli?

A. In my opinion these experiments do not exemplify the true conditions, the conditions which exist in the water of the drainage canal with relation to the life of the typhoid bacilli discharged into that as a part of the sewage.

Q. Upon what do you base this opinion?

A. The opinion is based on several points: First, the introduction of typhoid bacilli in an artificial culture in such a quantity of sewage enclosed in a parchment sac and protect it. This does not simulate the condition which would exist in the case of typhoid bacilli discharged into sewage and coming from a patient suffering from typhoid fever in which case the organisms might readily be and frequently are enclosed in fecal masses.

Further, the condition of the bacilli in this sac is quite different from that which they would be under if they were free in the stream where they would be free to settle, deposited in the sediment they might then become protected from the influence of the sewage upon them. 12726

Q. State whether or not in your opinion the fact that the bacterial and the chemical condition of the running water in the canal and river remain the same from one end of the day to the other, at the point where these parchment sacs may have been suspended in the water?

A. In my opinion the condition of the water would frequently change at any one spot owing, as I have said previously in my testimony, to the changeable condition of the discharge which we find coming from the sewers in Chicago.

Q. Would the fact that there is a different volume or quantity of sewage passing down at night than at day have any effect upon the chemical and bacterial changes of the water?

A. Yes, the difference in the flow between day and night would make a difference in the composition of the sewage water at any one place, and further, the flow at night is very different in composition from the flow during the day.

Q. Might not the fact, Doctor, that these bacteria were detained at one point in the parchment sac be harmful to them while if not so retained in the parchment sac they would 12727 pass further down the river, in a more favorable media and their longevity be preserved?

A. Yes sir. If the destructive action which was found in these cases to be exerted upon the bacilli was due in any way to the concentration of the sewage, the further the bacilli moved down the stream the less they would be subjected to this because of the increased dilution in the lower stretches of the river.

Q. Doctor, state whether or not in your opinion you know of any bacteriologists, epidemiologists or sanitarians who have limited the longevity of the life of the typhoid germ either in sewage or sewage polluted water to less than six days?

A. I know of no previous experiments which were of such a character as to warrant the experimenters for making such an assertion.

Q. Do you know of any expert as having written any article or expressed an opinion that the longevity of the ty- 12728 phoid fever germ in sewage or polluted water is within the limit of six days?

A. I do not recall any such limitations placed by any one.

Q. I will ask you to state whether or not, Doctor, from your researches in sanitary science and epidemiological work the opinions based upon the experiments of Doctors Zeit, Jordan and Russell wherein the longevity of the typhoid germ is limited to within six days do not stand by themselves and alone from all opinions that have been expressed and all determinations and observations that have been made by reputable sanitarians?

A. As far as I know this period of time is shorter than given by other authorities. Most experiments of this sort have demonstrated that sewage is in concentrated form detrimental to the life of the typhoid bacteria but the length of time which bacteria have lived in sewage of the different experiments have been so various that I do not recall a limitation expressed by any standard authorities on this subject.

Q. Doctor, I will ask you if you know of any instance
12729 where typhoid fever germs are known to have lived in sewage longer than six days?

A. Yes, there are published records of experiments showing the longer period than six days. To refresh my memory a moment the one set of experiments that I have in mind are those of Dr. Horrock's who showed that typhoid bacilli survived in unsterilized sewage a period of fourteen days and there have been other experiments made by different experimenters on this point.

As I state, I do not know of any one who has felt justified, as the result of these experiments, of limiting the period which typhoid bacilli might survive in sewage when they were introduced in what we might speak of as natural media and under natural conditions.

Q. You mean by unsterilized sewage ordinary sewage?

A. Yes sir, as contrasted with that in which other forms of bacteria have been destroyed before the other experiments have begun.

12730 Q. Doctor, Professor E. G. Smith who testified in this case for defendants was asked by defendants' counsel this question: "What do you say as to the assumption that typhoid germs could pass from the sewers of Chicago by way of the drainage canal to Lake Peoria and be deposited in the bed of Lake Peoria for the period of a month, as to whether or not the typhoid germs coming from the drainage canal under the conditions as they exist would live for the period of a month and not be destroyed at the end of that period," answered, and in his answer referred to the experiments conducted by Doctors Zeit, Jordan and Russell as follows: "In regard to the assump-

tion that typhoid germs could pass from the sewers of Chicago by way of the drainage canal to Lake Peoria and be deposited there in the bed of Lake Peoria for a period of a month, it is my opinion from my studies in regard to the purification of the stream embracing that knoweldge upon the analytical data submitted as evidence in this case, which data indicated the removal of sewagic bacteria before Lake Peoria is reached,
12731 it would follow that the typhoid germs from the sewage
of Chicago and the drainage canal do not reach as far as Peoria, and in further support of this view we have a deal of evidence secured by the results of the experiment upon the duration of the life of the typhoid fever germ showing that in the water of the river it does not live for a period of more than three or four days." I will ask you upon all the information that you have obtained from the study of the data introduced in evidence by respondent and found in the tables contained in Streams Examination, the report of the State Board of Health of the State of Illinois as contained in the testimony of Professor Long, the tables introduced in evidence by Professor Kinnicutt and the experiments of 1901 introduced in evidence by Professor Jordan, whether or not in your opinion you are able to say, taking into consideration also all that you have been able to observe upon the science of bacteriology and epidemiology, the period that the typhoid can be safely limited in the waters of the canal and the Illinois River at from three to four days?

12732 A. Taking into consideration the data to which you have called my attention and considering also the other facts which have come to my attention concerning the probable life of the typhoid bacilli after it has left the body of the patient, I would express it as my opinion that we would not be justified in concluding that the life of the typhoid bacilli would be limited to the period of three or four days under the conditions which are found to prevail in the drainage canal and in the Illinois River.

This conclusion would have to be based in my opinion, upon the evidence as shown in the chemical results that organic matter was so far decomposed as to admit no nutriment to these bacilli and that I can not see any justification for in the results.

As far as the bacteriological results go the deduction would have to be made from the experiments indicating the presence of small quantities of colon bacillus and the experiments in the sacs relating to the life of the typhoid bacilli under those conditions.

12733 In my opinion the experiments in those sacs deviate too far from the conditions which exist naturally and they are so much at variance with the ordinary experience which persons have had who have had to deal with the tracing of epidemics of typhoid fever, that they seem to me to afford facts altogether too incomplete to risk an opinion of such wide and far reaching importance as the decision that would follow in a case of this sort. The decision is too grave to be based upon any such experiment in my opinion.

Q. Doctor, in his testimony under date of March 1st, last, Professor E. G. Smith was asked by counsel for defendant the following question: "Assuming that the only pollution of the waters of the Mississippi River above the intake of the St. Louis waterworks derived from the sanitary district of Chicago, and having in mind a large amount of typhoid fever in Chicago, do you or do you not believe that infectious and dangerous pollution might, under existing conditions, find its way into the water supply of the city of St. Louis," answered as follows: "The evidence is already introduced in this case, both chemical

12734 and bacteriological, showing, in my opinion, some conclusions that the agency of self-purification above in this stream have practically transformed the sewagic matters from the city of Chicago before they reach Grafton, reducing the river at that point practically to the conditions of the streams, and the positive results secured in the experiments of Doctors Zeit, Jordan and Russell upon the viability of the typhoid fever germ in the polluted water of this stream, I do not believe that infected and dangerous pollution might, under existing conditions, find its way into the water supply of the city of St. Louis." I desire to ask you this same question, and ask you to take into consideration all of the matters contained in the tables found in Streams Examination introduced in evidence, the tables introduced by Professor Kinnicutt, the tables introduced by

Professor Jordan, outside of such tables as are prepared by him and found in Streams Examination, and also to take into consideration what bearing, if any, the experiments of Doctors Zeit, Jordan and Russell have upon actual conditions,
12735 and state whether or not in your opinion, under existing conditions, the infected and dangerous matter coming from the sewage of Chicago would find its way into the water supply of the city of St. Louis?

Mr. Todd: Object to the question upon the ground that the question asked, if it be the same question asked of Professor Smith, was a question prepared by counsel for the complainant and asked of Professor Sedgwick in his original examination when complainant was putting in their case in chief, and was asked of Professor Smith by the defendants by way of rebuttal to Professor Sedgwick's evidence, and now to ask this witness the same question which was gone into in chief by counsel for the complainant is not rebuttal evidence and is therefore incompetent, irrelevant and immaterial, and for the further reason it is an improper way to secure the opinions of this witness upon the original case of complainant by subjoining to the questions asked of Professor Sedgwick the testimony introduced in evidence by the defendants.

12736 A. Taking into consideration the various data to which you have called my attention, I would state that I have been able to find no evidence which to my mind is conclusive that the agencies at work in the stream are adequate to destroy the typhoid bacilli which undoubtedly are introduced into the sewage of Chicago and through it into the Illinois River, and therefore I believe that dangerous and infected pollution might reach the intake of the St. Louis waterworks.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Under the same assumptions, Doctor, as stated in the last question, do you or do you not believe that such infection and dangerous polluting matters coming from the sewers of Chicago do, under existing conditions, find their way into the water supply of the city of St. Louis?

Mr. Todd: Object to the question for the reason that this is not the time and place in the giving of testimony for com-

plainant to make out their case as this question was propounded to all the witnesses that complainant put on the stand in their
original case, and this is not proper rebuttal of any-
12737 thing that has been introduced in evidence and is there-
fore incompetent, irrelevant and immaterial.

A. In answer to your question I would state that considering all the data which I have been able to consider as bearing upon this problem, I believe that typhoid bacilli from the sewage of Chicago have reached the intake of the St. Louis waterworks.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Doctor, Professor Smith in his testimony under date of March 1st, was asked by counsel for defendants the following question: "Considering your personal knowledge as a sanitary expert of the typhoid conditions in the drainage district, the existing conditions in said city as to sewers and outfalls there and the amount of sewage and all existing conditions of the Desplaines, Illinois and Mississippi and Missouri Rivers, and all the conditions existing upon the watersheds of these streams and the tributaries thereof, and all conditions as to the water supply of the city of St. Louis, would you or would you
not, beyond a reasonable doubt, attribute the principal
12738 portion of the increase of typhoid fever of St. Louis to
the infected sewage of the sanitary district of Chicago, assuming that there has been an increase of typhoid in St. Louis since the opening of the drainage canal." Now, I will ask you to state, considering your knowledge as a sanitary expert of the typhoid conditions in the sanitary district of Chicago, your knowledge of the pollution and the amount of sewage deposited into the canal, and thence into the Illinois River from the sanitary district, under all existing conditions on the watershed of the streams of the Mississippi River and its tributaries above the chain of rocks, and all existing conditions as to the water supply of the city of St. Louis and the general sanitary conditions existing in St. Louis, do you or do you not, beyond a reasonable doubt, attribute the principal portion of the increase in typhoid fever in St. Louis to the infected sewage of the sanitary district of Chicago, also taking into consideration the re-

sults from the various analyses made by analysts who have testified in this case, as shown by the tables contained in the book known as Streams Examination, the report of the
12739 State Board of Health of the State of Illinois, and the tables introduced by Professor Kinnicutt and the tables introduced by Professor Jordan and the special experiments carried on by Professors Zeit, Jordan and Russell with reference to the longevity of the typhoid germ as contained in parchment sacs?

Mr. Todd: Object to the question for the reason that the question quoted as having been asked of Professor Smith was a question prepared by counsel for complainant and asked of Professor Sedgwick and George W. Fuller upon their examinations in chief by counsel for complainant and the second question following the question quoted is in substance the same questions propounded by counsel for complainant to all of complainant's witnesses in putting in complainant's case in chief, and is not rebuttal testimony of anything that is proper to be rebutted and is therefore introducing evidence of this witness upon the original case under the guise of rebuttal testimony which is incompetent, irrelevant and immaterial and not proper examination.

12740 A. I consider the problems involved in your question and would state that in my opinion the data available, especially those relating to the typhoid fever conditions upon the watershed of the Mississippi and Missouri Rivers above the intake of the St. Louis waterworks, and the data concerning the occurrence of typhoid fever in the Chicago sanitary district, are sufficient to demonstrate that the increase in typhoid fever has been due in considerable part at least to infection from the Chicago sewage.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: I will ask you to state, Doctor, whether or not you have examined the evidence introduced in this case upon the part of the complainant and the defendants as to the typhoid mortality in the city of St. Louis for the last six or eight years.

A. I have.

12741 Q. I will ask you to state, Doctor, bearing in mind the fact that in 1895 the intake of the waterworks of the city of St. Louis was changed from Bissell Point to the chain of rocks above the pollution of the Mississippi river by the city of St. Louis, to state whether in your opinion you consider it competent to compare the typhoid fever mortality of St. Louis previous to 1896 with that subsequent to that time in order to determine accurately and correctly whether or not an increase of typhoid deaths has taken place in the city of St. Louis since the opening of the drainage canal?

Mr. Todd: Object to the question on the ground that the whole question was gone into by complainants in their case in chief and it is not rebuttal, but merely accumulative and is therefore incompetent, irrelevant and immaterial.

Mr. Jeffries: In answer to counsel's objection I will say that defendants' witnesses in their testimony have insisted upon going back for a period prior to the change in actual conditions brought about by reason of the removal of the intake from Bissell's Point to the chain of rocks, being a well recognized fact that prior to the change the water of St. Louis was 12742 being polluted by the sewage of the city of St. Louis.

Mr. Todd: In reply counsel denies that the witnesses for defendants did anything of the kind; that the comparisons made by defendants' witnesses were limited to a period of four years before the opening of the drainage canal with the four years subsequent, and I would like to have the counsel specify the witnesses to whom he refers as having made such a comparison.

Mr. Jeffries: I will state that the record is plain and can be observed by the Court. Both Messrs. Jordan, Palmer and Barker, and even in counsel's cross-examination of complainant's rebuttal witnesses, taken at this session, he referred to conditions existing prior to the change of the St. Louis intake.

Mr. Todd: What counsel for defendant has done is not evidence in this case and he has not posed as a witness.

A. In reply I would state that it is my belief that a comparison of the typhoid fever death rates in St. Louis 12743 during the two periods, 1896 to 1899, inclusive, and 1900 to 1903, inclusive, is a competent method of deciding whether there has been an increase of typhoid fever in St. Louis.

And, further, I will state that in my belief this is the best method of testing the question as to whether there has been a change in the quality of the drinking water supplied to St. Louis with reference to its infection with typhoid fever.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. You mean by your answer that the manner suggested by you in the answer is the best method?

Mr. Todd: Object to the question for the same reasons as well as its form.

A. I mean that the comparison of the typhoid death rate in St. Louis for the two periods is the best method of ascertaining the conditions of the drinking water of St. Louis with reference to this period, of course using in connection with that the data concerning the upper watershed.

Mr. Todd: I move to strike out the answer for the same
12744 reason stated in the objection.

Mr. Jeffries: Q. I will ask you to state, Doctor, whether in your opinion and judgment there has been an increase in the mortality from typhoid fever in St. Louis since the opening of the drainage canal as compared to mortality for the same number of years immediately prior to the opening, such increase being based upon the typhoid mortality per 100,000 or based upon the percentage typhoid mortality.

Mr. Todd: Object to the question for the reason that this question has been put to nearly every witness offered in this case by complainant and is the very basis upon which complainant predicates its case and is not rebuttal, but a part of the original case and therefore is incompetent, irrelevant and immaterial, and is an improper question.

A. In my opinion there has been an increase in the typhoid death rate in St. Louis, based upon the mortality per 100,000 population or upon the percentage of typhoid deaths to the total mortality.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

12745 Mr. Jeffries: Q. Upon what facts in evidence do you base this opinion?

A. I base this opinion upon the study of the facts presented from compilations as to the death rates made from the records of the mortuary office and a comparison of the rates for the two periods.

Mr. Todd: I move to strike out the answer for the reasons given in my objection to the question, and for the further reason it is not competent for the witness to testify from any records that have not been proven in evidence.

Mr. Jeffries: I will state, for the benefit of counsel, that such testimony as referred to by the witness will, under the rule that has been adopted by counsel for the respondents for the introduction of their testimony, be shown in evidence later on.

Mr. Todd: Assuming the comity existing between counsel, the answer is not competent for the reason given in my objection.

12746 Mr. Jeffries: Q. State, Doctor, whether or not you have examined the testimony introduced in evidence here by respondents showing from the published reports of the Health Commissioner of St. Louis, the total number of deaths reported from remittent, intermittent, typho-malaria, congestive and simple continued fevers, and state whether or not you have examined the compilations taken from the original record in the office of the mortuary officer of the city board of health and made a comparison as to the total number of deaths so reported by respondent's testimony upon these various and respective diseases now designated as nondescript, and state whether or not upon your examination of these records there has been, in your judgment or opinion, an increase in the typhoid in the city of St. Louis since the opening of the drainage canal?

Mr. Todd: Object to the question for the reason that it is not rebuttal; for the additional reason it is incompetent, irrelevant and immaterial and that the records are the best evidence.

12747 A. I have examined the data given in the Health Commissioner's report and also those given in the compilation from the mortuary office referred to and have compared the data, and would state that it is my opinion, based upon these examinations and comparisons that there has been an increase in the typhoid death rate in St. Louis during the period covered by the four years, 1900 to 1903, inclusive.

Mr. Todd: I move to strike out the answer for the reasons assigned in my objection to the question.

Mr. Jeffries: Q. This compilation from the records of the mortuary office of which you speak is the one represented to you as being prepared by Mr. Lochridge, is it not?

A. That is the compilation which I referred to.

Q. And Professor Sedgwick—Mr. Lochredge and Professor Sedgwick?

A. Yes sir, I understood the compilation was effected by both, and shown me by Mr. Lochredge in particular.

Q. State, Doctor, whether or not the increase in typhoid fever deaths in the city of St. Louis since the opening of the drainage canal as compared to the same number of years immediately prior thereto has been a decided increase?,

12748 Mr. Todd: Object to the question for the reason that it is not rebuttal as the same subject has been gone into in chief by complainant's witnesses and is therefore incompetent, irrelevant and immaterial.

A. I would state that the comparisons which I have made indicate that the increase has been a very considerable one.

Mr. Todd: I move to strike out the answer for the reasons indicated in my objection.

Mr. Jeffries: Q. State whether or not an increase in typhoid fever in St. Louis since the opening of the canal is shown to any considerable extent during the winter months?

Mr. Todd: Object to the question for the same reasons as heretofore stated.

A. I would state that the increase has been more noticeable during the winter and spring months than it has during the summer and autumn months.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection.

Mr. Jeffries: Q. Doctor, are you acquainted with what 12749 is known as the Widal test?

A. I am.

Q. Please state the purpose for which this test is used?

A. It is used as one of the aids in the diagnosis of typhoid fever.

Q. Will you state as a physician and sanitary expert what effect if any the use of the Widal test may have upon the reports of typhoid fever deaths by physicians?

A. I think that the use of the Widal test has probably not affected very materially the reports of deaths of typhoid fever. Its influence has been more marked in the matter of correct diagnosis of the milder cases of typhoid fever.

Q. Doctor, I will ask you to state whether or not it is usual in all large communities and cities for health authorities to issue circulars urging physicians to report cases of deaths of typhoid fever to them?

Mr. Todd: Object to the question as it is incompetent, irrelevant and immaterial and not proper rebuttal evidence.

A. Boards of health in large cities usually have regula-
12750 tions relating to the reporting of lists of certain diseases
and among these typhoid fever is always included, and it is common for the boards of health to issue circulars to physicians calling to their attention the regulations pertaining to the report of such cases.

Mr. Todd: I move to strike out the last answer for the reasons stated in my objection to the question, for the same reason as the other objection.

Mr. Jeffries: Q. What in your opinion is the effect of the issuance of such circulars upon the typhoid fever death statistics of these communities and large cities to which you referred in your last answer?

Mr. Todd: I object to the question for the same reason as stated in my former objection.

A. As the circulars relate to the reporting of cases and not at all to the reporting of deaths, and as deaths are usually reported to some regular office, and in many instances separate from the board of health, I see no reason why there should be
any special effects shown in the reporting of deaths from
12751 typhoid fever from such circulars, and I have in my ex-
perience not seen any occurrence which would lead me to suppose that there was any such general effect.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Doctor, at what ages do the most of the deaths from typhoid fever occur?

A. The ages of most susceptibility to the typhoid fever are from fifteen to thirty, though there are many cases between ten and forty, the cases under ten and over forty being less common than in the other decade.

Q. Is not the disease rare in infants or persons over sixty years of age?

A. Yes sir, the disease is comparatively rare at these ages.

Q. Doctor, I will ask you if in your professional work you have become associated with the cost, manner of operation and cost of operation of filtration plants?

A. I have had occasion to consider the cost of operating filtration plants, especially as related to the expert over-
12752 sight of their operation, this having come to my attention through my connection with several water companies.

Q. Doctor, taking into consideration all the analytical data introduced in evidence by defendants and found in Streams Examination or otherwise, and taking into consideration the fact that Chicago sewage is discharged into the Illinois River by means of the drainage canal, and that the sanitary district of Chicago has a population of more than 1,700,000, which is constantly and rapidly increasing, and taking into consideration the bacterial and chemical results shown from the analysis introduced in evidences, taking into consideration the physical surroundings and conditions existing upon the Illinois River and the Mississippi River watershed above the chain of rocks at all times and all seasons of the year, I will ask you to state whether or not if a filtration plant should be established at St. Louis, the cost of its operation would be increased on account of the opening of the drainage canal and the passage of the sewage from the city of Chicago and the sanitary district of Chicago through the canal into the Illinois River, and taking into
12753 consideration the fact of this large amount of sewage continuously being discharged from the city of Chicago, state whether or not the operation of such a plant would require less cost if the deleterious and dangerous and infectious substances contained in the waters discharged from the canal into the river were eliminated from that river?

Mr. Todd: I object to the question for the reason that complainant went into the subject of the cost of filtration in their original case with the witnesses Professor Sedgwick and Professor Fuller, and it is not competent to introduce evidence upon the subject in rebuttal, and it is therefore incompetent, irrelevant and immaterial.

A. Taking into consideration the facts which you have called to my attention, I would state it as my opinion that the installation and operation of a filter plant at St. Louis would be more expensive by reason of the discharge of the sewage from Chicago into the Illinois River and that if the deleterious agents in this sewage were removed that the cost of the installation and the maintenance of a filter plant at St. Louis would be
12754 lessened.

ADJOURNED until 10:00 a. m., Wednesday, May 25, 1904.

12755 10:00 a. m., Wednesday, May 25, 1904. Room 282 Southern Hotel, St. Louis, Mo. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

DR. HERBERT E. SMITH

resumed the stand for cross-examination by Mr. Todd, and testified as follows:

Q. Doctor, have you ever made a chemical and bacteriological survey of a river as long as the Illinois River and of equal flow?

A. I have never made an examination of the whole course of a river as long as the Illinois River, but I have made frequent analyses, covering several years, of the Connecticut River in that part which goes through the state of Connecticut.

Q. In making a chemical and bacteriological survey of a river, what method would you adopt in order to show the true condition of that river at all times and throughout all seasons of the year?

A. By chemical and bacteriological survey I understand you to mean analyses. I would reply to that that it is not possible by any kind of analysis, chemical and bacteriological, to arrive at a positive conclusion as to the condition of a river at all times and all seasons.

The reason that I answer that way is that there are
12756 two problems involved. The problem of sampling—it is
possible to sample a river in such a way as to represent the water pretty closely which passes through that river, but that means taking continuous samples, and samples in quantities proportional to the flow and that is impracticable in a large stream, but the other reason why it is impossible to come to such a conclusion is embodied in my answer to a question yesterday, that chemical and bacteriological analysis alone can not show the true sanitary condition at all times and seasons, of the river.

Q. What do you mean by taking samples proportional to the volume of the river?

A. I mean this, that if a stream is flowing, to assume 1,000 gallons a minute at one point in a small stream, and you take a gallon sample of that stream flowing 2,000 gallons, you ought to take two gallons.

Q. How would you be able to analyze a gallon sample, chemically and bacterially?

A. You have to take a sample of the water of the gallon
12757 for definite determinations and that sample has to be
taken by a thorough mixing of the sample. It is still, however, only a sample of the whole. As far as the chemical features are concerned, that can be diffused equally through the volume, so that a sample of say a half liter will represent the chemical composition of the whole.

As far as bacteriological samples are concerned, it is exceedingly difficult.

Q. Would not the samples bear the same relation to the two gallons as the samples taken out of the river in small quantities would be to the river at the same time and place?

A. Precisely the same proportion, but the results have to be considered in making an average. That is, you would have to give twice the value in making your average on the sample collected when the flow was 2,000 cc. per minute than you would when the flow was 1,000.

Q. How often would you take these samples?

A. I have stated if you want to get a result from a thorough sampling, you have to take them continuously.

12758 Q. How often continuously—every five minutes?

A. There is only one way to take a continuous sample, and that is to have some sort of a weir arrangement which will give you a continuous flow, one portion coming into your sample bottle and the other portion going on down the river. There is no way of taking a sample every five minutes or every hour or every week which will fully represent the sample.

Of course you will approximate to it the more frequently you take it.

Q. In the examination which you made of the Connecticut River did you pursue there that method?

A. Not by any means. There was no attempt to make a thorough determination of the sanitary condition of that river at all times.

Q. Do you know of any analysist of waters who has pursued such a course in Europe or in this country, according to the methods which you prescribe?

A. No sir, I do not and I should say that no one would be likely to recommend such a thing because the results obtained by those methods would not be comparable to the experi-

12759 ence of course—in other words the method is required to solve problems.

Q. In other words you are giving the ideal method regardless of experience?

A. The ideal method would be that which you have asked for, which, in my opinion, is an ideal method and which can not be solved by the limitations of the bacteriologists and chemical analysists which you have asked me to consider.

Q. Such a method would be true as to one point in a river would it not, but would not be true as to all points in a river one hundred miles long?

A. If you wish to sample a stream at any point and get a set of figures which will represent accurately the condition of that stream at different points, you would have to at every point.

Q. Would you not also have to take samples at different depths?

A. Yes sir.

Q. So that in a stream one hundred miles long your stations would have to be located nearer than five miles apart in order to get a perfect accurate determination?

12760 A. Assume that you could get an accurate determination, I should say that the nearer the stations were together the more closely you would approximate to that result, but the location of the stations and the distance between them would depend upon the surroundings as to whether there was water flowing in from other tributaries and so on.

Q. In your investigations of the Connecticut River, how often did you take the samples?

A. These samples were taken only once a month.

Q. And was that often enough to enable you to give an opinion as to the quality of the water of the Connecticut River?

A. No sir, and I did not attempt such an opinion, based upon those analyses.

Q. What purpose did you have in taking the samples once a month if it was not for the purpose of forming an opinion as to the condition of the river?

A. It was with a view of obtaining the data showing the general character of the water flowing in the river, but it was not an attempt to ascertain the character of the flow at all times and all seasons. There was no reason for it.

12761 Q. Did you make a bacteriological examination of that river?

A. I have of water from that river.

Q. Did you make a bacteriological examination of the waters of that river covering the periods that you made the examination?

A. No sir.

Q. What other rivers, Doctor, have you made any chemical or bacteriological survey of, in this country?

A. Assuming again that you mean analysis by the word survey, I have made chemical analysis of samples of water from the Nantucket River, the Still River, the Thames and the various tributaries flowing into it, the Hockanum, and numbers of other samples were sent to me from outside of the state which I do not recall the situation of.

Q. What I mean by chemical survey, Doctor, is not the analysis of a few samples, but the analysis of a number of samples of the river throughout its entire length in order to ascertain the general character of the waters of the river. Have you made any such chemical or bacteriological survey of any river?

Mr. Jeffries: Object to the question for the reason the 12762 witness has already stated that the character of the water can not be accurately obtained from the chemical survey it matters not how frequently samples may be obtained and analyzed.

A. Those that I have enumerated, I have made frequent determinations, some running over periods of three years, monthly samples, and for the purpose of showing the general chemical character of the water, but not for the purpose of showing all the details of the sanitary condition of the river. There have been analyses in connection with the rivers pollution of the State of Connecticut and have been for the most part with reference to the manufacturing wastes.

Q. At how many points in the Connecticut River were samples taken?

A. They were taken at four stations.

Q. How long is the Connecticut River?

A. In Connecticut it is about seventy-five miles.

Q. Did you make any other surveys, using the word in the sense that I have explained it, of any other river then the Connecticut River?

A. The analysis made of the Nantucket River extended 12763 over a period of four years, I think.

The Still River was made at periods covering perhaps three years, and the others that I have named of the sewage polluted streams in Connecticut, mostly cover periods of a year.

I would say in this connection, that I may not be misunderstood, that none of these streams are used for drinking supplies and the problem was not as to the suitability of the water for drinking.

The Connecticut is the only one of these that has been used, and that is not now in use for that purpose.

Q. Have you made any experiments upon sewage disposal?

A. You mean experiments or analysis?

Q. Experiments and analysis?

A. I have made analysis of sewage and analysis of the effluent of sewage beds for a number of different sewage purification works, but I have never entered into series of experiments for determining methods of purification.

Q. Have you had any experience in the operation and management of what is known as sèptic tanks?

12764 A. No sir.

Q. Have you studied the septic operation of these tanks, personally?

A. Not in the way of making analysis, no sir.

Q. Have you visited any septic tanks for the purpose of studying their operation?

A. Not any large tanks which were taking the sewage of any considerable community as they are, but of those located in the East. There are one or two small places that I have examined. We have one near New Haven which, as it is run, it is practically a septic tank, or comes pretty near it in its operation of being a cess pool.

Q. Do you regard yourself as an expert on septic tanks?

A. I consider that by my study of the subject I understand pretty well the chemical and bacterial theory of a septic tank but I should not undertake to agree to discuss the engineering features of the construction of a septic tank. That is not in the scope of my work at all.

12765 Q. In giving your opinion upon the tables referred to in your testimony, as introduced in evidence by Professor Kinnicutt, in regard to conditions that obtained in the drainage canal, I understood you to say that those tables were not sufficient to enable you to pass a satisfactory opinion upon the elimination of the pathogenic bacteria in the waters of the drainage canal, and in expressing that opinion you confined it purely to yourself and not to what others may be able to do from those tables, do you not, Doctor?

Mr. Jeffries: Object to the question for the reason it is duplex and misleading.

A. In making the reply I referred to what I could do with these data, basing it upon the evidence which I have found in the literature which goes to show that the knowledge of what destructive action takes place in septic tanks is not yet complete, and in this point I agree thoroughly with the statement made in the testimony of Professor Kinnicutt, when he states that the experiments on this point are not very numerous.

Q. In your testimony in regard to the tables of Professor Kinnicutt, in connection with the drainage canal, your 12766 opinion was based upon the efficiency of the drainage canal as an apparatus for the purification of sewage was it not?

A. My opinion was based upon the data shown in the tables introduced in that connection, and what I know about the operation of septic tanks as to the efficiency of that particular apparatus as a sanitary appliance.

Q. Would you say from the tables that sewage is not reduced considerably from the time it enters the drainage canal• until it leaves the canal at Lockport?

A. From the evidence given in the tables I should say that there was a very considerable reduction in the constituents of the sewage between the two points named and so testified.

Q. Is there any septic action taking place in the drainage canal?

A. According to the tables, especially the table E, which is a comparison of the loss in certain ingredients in that tank as compared with the loss in certain other specified septic 12767 tanks, there is a loss which is to be accounted for by the bacteriological action which takes place and is responsible for the beneficial action of septic tanks.

Q. Is that what is commonly known as septic action?

A. It is.

Q. In looking over Professor Kinnicutt's tables, did you take into consideration his personal knowledge and personal observation of the drainage canal as testified to by him in his testimony in interpreting his tables?

A. In the answer to the question which you have referred to, I think I was confined to a consideration of the tables, but in the answer which I gave you a few minutes ago, when I said I agreed with Professor Kinnicutt as to a statement which he made about the experimental knowledge of the action of septic tanks, I, of course, took that into consideration in stating as I did a few minutes ago that the action shown of the tanks was of a septic character.

12768 Q. Are you acquainted with the physical conditions of the Illinois River from Joliet to Grafton?

A. In a general way, as testified, yes sir, I am.

Q. What is the effect of an increased speed in the character of the Illinois River?

A. The effect of an increased speed in the current of the Illinois River would be to hasten the passage of the water from the upper reaches to the discharge, and also to lower the point where the most active oxidation effects take place, and also to carry down any matter which was suspended and which otherwise would tend to sink.

Q. What is the fall of the Illinois River from La Salle to Grafton?

A. I do not know the exact fall, but it is, according to my recollection, about thirty feet.

Q. Are you acquainted with the banks of the Illinois River?

A. In a general way, by description.

12769 Q. Are you acquainted with the condition of the Illinois River prior to the opening of the drainage canal?

A. In a general way, by description, especially by description, and according to my knowledge that condition was in a general way described in a question at length, which I had yesterday.

Q. Will you give me your ideas of the Illinois River prior to the opening of the canal, throughout the year, as to the different stages of the water?

A. I understand that there was a very considerable difference in the flow ni the Illinois River due to different stages from the various tributaries at different times of the year, but that there were certain periods when the flow was very slight, and I base this opinion upon the sort of information which I have received and which was practically embodied in the question referred to in my answer to your last question.

12770 Q. Did you understand that that condition obtained for any considerable period of the year?

A. My understanding was that the stagnant condition was practically a warm weather condition.

Q. Are you acquainted with the flow conditions of the Illinois River prior to the opening of the drainage canal?

A. In a general way I am, and this was indicated in my answer that I understand there is considerable variation from the discharge of the other rivers and also upon my study of the tables which were presented in the book of Streams Examination which tables show a very great variation in the height of the water and also in the amount of sediment which is carried and both of these, of course, are conditions indicating large water flow.

Q. Have you read the guage readings that have been offered in evidence by both sides in this case?

A. I have not, unless you refer to the column marked height in the table in streams data. I note a number of them.

12771 Q. Professor, are you aware that the flood conditions prior to the opening of the canal were as great as they have been since the opening of the canal at times?

A. Yes sir, I understood that the flood conditions prior to the opening of the canal had been at times greater than the maximum at times since the opening of the canal, and this variance is the result of rainfall and would vary from year to year surely.

Q. What effect do flood conditions in the Illinois River have upon the surrounding country?

A. There are two effects of a flood in the Illinois River and other rivers of the same general physical condition.

One is that the low country is flooded by reason of the incapacity of the water course to take off the flood water and it therefore backs up, and the other is that owing to the rush of waters there is a larger amount than usual of sediment which is swept down the stream. Those are the two essential
12772 things.

Q. What other river in the country that you are acquainted with other than the Illinois River?

A. In making use of that term I referred to the conditions of low banks and the conditions of a variable fall upon the water shed and most of the smaller streams with which I am familiar are subject to that sort of flood.

Q. Do you know of any river in this country that for a distance equal to that from La Salle to Grafton, as large as the Illinois River, that has a fall of only 30 or 40 feet?

A. I can not answer your question with regard to feet because I have, of course, given no attention to the general hydraulic conditions. In a general way I should say that there were a number of rivers on the western plains, the Arkansas for instance, where there would be a very small fall, and I think it would be as small as that, but I can not give the exact figures.

Q. Do you know how many acres of land is inundated along the Illinois River when the stream rises above its bank at flood times?

12773 A. I think I have seen some statement which gave the impression that it was a large number of acres, but I can not quote the number.

Q. By large number, what do you mean, Doctor?

A. Well, I am unable to state in acreage, and if you desire that figure, I shall have to be allowed to present it.

Q. Will it run up into the hundreds of thousands of acres? That is, I mean the land on the Illinois River subject to over flow?

A. If you will permit, I shall desire not to express an opinion, when I can present the figures.

Q. It has been testified here there are about 300,000 acres of land subject to overflow along the Illinois River. At the time of such overflow, when the rate of time for passage from Chicago to St. Louis is at its minimum, what effect do these over flowed lands have on the question of sedimentation?

Mr. Jeffries: Object to the question unless it includes sedimentation in the bed of the stream, the effect of sedimentation upon the bed of the stream as well as upon the overflowed

12774 lands.

A. There are two effects of the over flooding of a stream by a large amount of water. One is that the sediment of the stream is in part distributed throughout the bulk of the territory which is covered and the water being less turbid in those particular parts there is an accumulation of the sediment upon those parts or areas.

The other effect is that owing to the increased height of the water there is a more rapid flow in the channel of the river so that under those conditions there is a tendency to scour out the sediment, part of which is distributed and another portion carried down through the channel.

Q. Professor, in studying the analytical data of the Illinois River, did you see the tables of analysis introduced in evidence by Professor Palmer, that were not published in Streams Examination?

A. I have examined, in addition to those given in Streams Examination, the tables given in the Illinois State Board of Health report and in the publication by the University of 12775 Illinois.

Q. Did you take the analysis of Professor Palmer into consideration in giving your testimony in chief?

A. In giving my testimony as to the sanitary condition of the stream as judged from the tables and what other tables of chemical analysis and what other information I had concerning them.

Q. Did you examine the analytical data of Professor Teichmann the chemist for the State of Missouri?

Mr. Jeffries: I object to the question for the reason that that was not gone into in chief, and for the reason it would have been incompetent had he examined it.

A. I do not recall that I have seen that.

Q. Of Professors Ravold and Keiser?

A. No sir.

Q. So then in answer to the question, where the clause "Other information that you had" the analytical data of Teichmann, Keiser and Ravold were not considered by you under that clause?

A. No sir.

12776 Q. You are acquainted with the water shed of the Mississippi River prior to and since the opening of the drainage canal are you not?

A. In a general way, I have a number of times crossed it and in a general way I know the conditions.

Q. Prior to January, 1900, would you consider the Missouri as a safe water, for domestic and drinking purposes in its raw state?

Mr. Jeffries: Objected to as immaterial.

A. In its raw state I would not recommend the stream referred to for drinking water to any community.

Q. Would you recommend the Missouri River water as treated by the settling basins in St. Louis as a safe drinking water, for drinking and domestic purposes, before the opening of the drainage canal?

Mr. Jeffries: Objected to as immaterial, and in contention
of my objection to the question asking this witness
12777 whether or not he would recommend the waters of the
Illinois River prior to the opening of the canal, suitable for domestic purposes, I move for judgment on the grounds that under the evidence of respondent which shows that the addition of the lake water has preserved the longevity of the typhoid germ over conditions which existed in the Chicago River prior to the discharge of the 250,000 cubic feet of water per minute in that canal, and for the further reason that the testimony of respondent taken down the Illinois River shows that the saprophytic and other conditions for the destruction of pathogenic bacteria and substances was far greater and far better than under the conditions existing today, since the opening of the drainage canal, and that under conditions now existing the life of the germ coming from Chicago and at other points on the Des Plaines and elsewhere is prolonged, and that the testimony of respondent is to the effect that by reason of the longer preservation and prolongation of the life of pathogenic bacteria, there is more danger and more impending harm hanging over the
inhabitants of the State of Missouri and the City of St.
12778 Louis using and drinking the waters of the Mississippi
River by reason of the discharge of the waters of the Illinois River into it than existed prior thereto.

Also object to the question as immaterial.

Mr. Todd: I move to strike out all that counsel has said as having no bearing upon the subject.

Q. Question read.

A. In answering that question, I must assume that the water treated in the sedimentation tanks for the water supply of St. Louis is the Missouri River water. Under this understanding I would say that my recommendation would have to include two

considerations. If it were feasible to recommend an ideal water supply, under all considerations, I should recommend that the water of the Missouri River be treated more efficiently than by the sedimentation tanks, but I should also have to consider that the statistics of the typhoid fever rate which, in my opinion, is on the whole the best test of the sanitary condition of the drink-
ing water during the four years, 1896 to 1899, inclusive,
12779 would indicate that the water at that time was in a pretty
satisfactory sanitary condition, and if it was not possible
to have the ideal condition, I would be willing to recommend under those conditions the continued careful use of the present sedimentation system.

Q. Are you acquainted with the sedimentation basins in the city of St. Louis and how long the water remains in those settling basins before it is distributed to the consumers?

A. I am acquainted by having seen them some time ago, but have not made a careful investigation of their action, nor do I know their rate of flow.

In expressing the opinion which I did in reply to your last question, I have considered the results of the action of their treatment as indicated by the test which I referred to in the examination of the typhoid death rate.

Q. Would you recommend that river water for drinking and domestic purposes that has the population upon the water
shed such as the Missouri River has, which is only treated
12780 with settling basins, when the water does not remain in a
quiescent state to exceed three days for drinking and domestic purposes?

Mr. Jeffries: Objected to as immaterial.

A. In reply to your quesction I should have to refer you to my answer to your previous question as to the recommendation of the Missouri River water, and would state again that if it were feasible to obtain an ideal water supply, I should recommend the installation of much more efficient purifying apparatus, but in view of the typhoid statistics I might recommend the continuance of the present system under careful oversight.

Mr. Todd: Q. Do you know how far Kansas City is located from the intake tower of the St. Louis water works in point of time?

A. I have had the data before me.

Q. Well, assuming, Doctor, that the distance of Kansas City is from four to six days from the intake tower of the city of St. Louis, and the city of St. Charles is about forty miles above the intake tower, where it has an open system of sewage, and has typhoid death rate there some years up to twenty 12781 deaths within the last five years, and assume that the total number of deaths on the water shed of the Missouri River within a distance of fifteen days for the years '97 was 97 deaths, 1898 was 118 deaths, 1899 was 158 deaths, which were traceable in the cities of Lincoln, Omaha, Council Bluffs, St. Joseph and Kansas City, and that the water of the Missouri River was treated as it is now treated by the settling basins in St. Louis during that period, would you recommend the water of the Missouri River thus treated as a safe drinking water for drinking and domestic purposes taking into consideration all that you know about other typhoid conditions on the water shed of the Missouri River, as well as the physical and hydraulic conditions of the river, both rural and urban?

Mr. Jeffries: Objected to as immaterial.

A. Replying to your question I would again refer you to my answer on the original question as to recommending the water of the Missouri River, and would state again that the consideration and the data which you have presented to my attention would certainly lead me to the opinion that the water 12782 is not an ideal water for a public drinking supply, but I would again state that the typhoid fever statistics during this period compare so favorably with those of other cities having reasonably good water supplies that I might recommend the continued use of the water even in view of the facts which you have presented to me.

I would again emphasize that part of the answer which refers to the necessity of operating such a plant with caution.

Mr. Todd: Q. My question, Doctor, eliminates the Mississippi and the Illinois River waters and simply deals with the Missouri River water in the condition that it existed at that time and does not ask for an ideal water supply, but simply asked you whether you would recommend that water, knowing the conditions that obtain upon the water shed, and knowing the treatment that such a water would receive from the settling basins of the city of St. Louis, as a safe drinking water for 12783 drinking and domestic purposes, as it comes from the hydrant.

A. Replying to your question I would say that I took into consideration by the original assumption that the water was the Missouri River water, and I took into consideration the question that such a water is not absolutely safe and therefore not ideal, but that under conditions as they exist, the actual operation of the plant during the period which you refer to as shown by the typhoid statistics indicates that the water was a reasonably safe water supply at that time and my opinion which I have given throughout here is based upon the effect of the water after the purification which the treatment seems to have been adequate and complete as indicated by that test.

Q. Would you recommend such a water so treated as a safe drinking water for domestic and drinking purposes?

Mr. Jeffries: Object to the question for the reason it has been answered.

Mr. Todd: I contend it has not.

A. Replying to your question I would say that I do not consider such a water an absolutely safe water and that there are very few absolutely safe waters, even waters which have 12784 had a certain amount of contamination and are filtered are not absolutely safe. Such things are not accomplished readily. One has to decide as to the reasonable safety of all conditions and this, I consider, has been shown during the years in question by the statistics which have been quoted.

Q. As sanitarian would you recommend that water for drinking and domestic purposes of the Missouri River, treated in the settling basins in St. Louis?

A. As stated in my original answer that must depend somewhat upon the conditions. If it is not feasible to acquire an ideal purification plant, then in view of the knowledge which I have as to the efficiency which has been shown by the purification plant, I would recommend it as one which might be used under the same conditions with reasonable safety.

Q. Would you drink the water and have your family drink it, coming from the Missouri River, passing through settling basins and delivered out of the hydrant?

12785 Mr. Jeffries: Object to the question for the reason that the question is confined personally to the witness's own personal use while we are dealing with a question looking towards the betterment of conditions generally, taking into consideration the character of the people and the extent of the population of the city using a water for domestic purposes and that the question involved is one of practicability, construed in the light of sanitary science as it exists today throughout the United States and that the sanitary condition of a water to be used as a public supply can not by reason of all the physical circumstances surrounding the various rivers throughout the United States, be compared or placed upon a level with the individual opinions and personal preference of any one particular user of that water, but must be construed in the light of the science as it exists today and as it is applied to the subject of water supply.

Q. Question read.

A. In reply I would refer you to my statement that I would recommend the water as a reasonably safe water that personally knowing the dangers of typhoid infection and having in 12786 my family young persons of the age which is particularly susceptible to the infection of typhoid fever, I should hesitate myself to use it or have my family use it, and would not do so under ordinary conditions, but I should have to recognize and did recognize, in giving the opinion that I could recommend the water as a reasonably safe water, that the average community in the United States do not as yet accept as high a standard for their requirement of a drinking water as I should with my own knowledge for my own individual use.

Mr. Todd: Q. That being the case, Doctor, assuming that the community of St. Louis should entrust the securing of a water supply for their people to you, and you were selected as a sanitary expert, knowing the conditions that obtain upon the Missouri River and in the city of St. Louis would you recommend to the people and put yourself on record as a sanitary expert recommending the waters of the Missouri River as a safe drinking water, treated as it is in settling basins?

Mr. Jeffries: Object to the question for the reason that the witness has already answered the question and stated his 12787 reasons for the answer, and for the further reason that sanitary experts as a rule are required, because of public necessity, to make such recommendations looking towards the health of the community in question as they may see fit and that it is afterwards the right of the community to determine whether or not the recommendations shall be carried out or which set of recommendations will be carried out and observed by them.

Mr. Todd: Q. Divorcing your answer to my question from all recommendations whether it be carried out or not, but simply giving your answer as a sanitarian, assuming the conditions in the question, would you recommend the waters of the Missouri River to the people of St. Louis, treated in the settling basins as it is today, as a safe water for drinking and domestic purposes?

A. Replying to your question I would again refer you to my repeated statements that I could recommend the water of the Missouri River, under my original assumption, as it existed during the years 1896 to 1899, as a reasonably safe water. That I do not consider it an ideal water.

12788 Assuming that I was forced to express an opinion as to whether the water were absolutely safe, and that I was not permitted and not desired to recommend anything except an absolutely safe water, I would not recommend this water as an absolutely safe water.

Q. Do you regard the Mississippi River water above Grafton if treated in the same manner with the apparatus of the settling basins as a safe drinking water for drinking and domestic purposes, to be used by the citizens of the city of St. Louis?

A. In answer to your question I would state that according to my understanding of the situation existing at St. Louis, the water supply of the city of St. Louis during the period of four years which we have been discussing, and that subsequently the questions of its sanitary condition as affected by the processes of purification as carried on at St. Louis is to be judged by the same test as applied to the Missouri River.

Q. Assuming, Doctor, that the drainage canal should be closed and none of the sewage from Chicago should come

12789 by way of the drainage canal or the Illinois and Michigan Canal, would you recommend the water of the Mississippi River today, being a mixture of the Missouri, Mississippi and Illinois River water after it passed through the settling basins of the city of St. Louis as of today as a safe drinking water for drinking and domestic purposes?

Mr. Jeffries: Object to the question for the same reasons.

A. Replying to your question I would say that according to my understanding the areas referred to, discharged from the Illinois River into the Mississippi River and that from land tributary to the water supply of St. Louis during the period 1896 to 1899, and that therefore my conclusions with regard to the Missouri River water as affected by the process of purification in vogue at St. Louis during that period would also have to include this area.

Mr. Todd: Q. My question is, Doctor, would you recommend the water with the entire population of Chicago excluded, after it passed through the settling basins, knowing as

12790 you do the typhoid conditions that exist upon the three water sheds, knowing as you do the distances in time from Minneapolis and St. Paul, from Peoria to St. Louis, from Lincoln, Nebraska, to St. Louis, as a safe drinking water for drinking and domestic purposes?

Mr. Jeffries: Object to the question for the reason that it is immaterial and for the further reason that the witness has already answered the question and stated that so far as this question is concerned he made the same answer as to the question referring to the Missouri River alone.

Mr. Todd: I submit that the witness has not stated whether he would recommend the water as a safe drinking water for drinking and domestic purposes, and that it is the question that I have asked repeatedly, and it is the question that I ask now, and I have a right to have a definite answer to my question as he is an expert on sanitary science.

Mr. Jeffries: I will suggest to counsel that witness has answered the question time and again, but I object to counsel

12791 insisting upon witness answering the question as he desires or having counsel to put the answer in witness's mouth.

Q. Question read.

A. Replying to your question I would state that I understand that the conditions enumerated in your question indicating the discharge of sewage throughout the water shed above the chain of rocks at the point where the St. Louis water supply is taken was, during the period 1896 to 1899, excepting that during that period there was a certain amount of discharge of the sewage of Chicago into this area, and under this understanding I would again refer you to my previous answers as to my opinion concerning the recommendation of the Missouri River water and the discussion following as in my opinion answering your question.

Mr. Todd: Q. Doctor, do you mean that you would recommend the water of the Mississippi River as it passes through the settling basins to the city of St. Louis as a safe drinking water for drinking and domestic purposes, assuming that the entire sewage of Chicago should be eliminated?

A. Replying to your question I would state that I have 12792 already answered that the water supply which was used in St. Louis during the period in question gave such results according to the test of the typhoid fever death rate that in my opinion, as I have stated, it was during that time a reasonably safe water and I understand that during that period a part of the Chiego sewage was discharged into the river. The removal of that would of course not, affect my opinion as already expressed, so that I would state explicity that I would not recommend, as already stated, the water in use at that time as an absolutely safe water but the results of the tests are, in my opinion, sufficient to justify one in recommending it as a reasonably safe water.

Q. Would you recommend it now as a safe, not reasonably safe, as a safe drinking water for drinking and domestic purposes if the entire sewage of the sanitary district of Chicago was eliminated, treated as it is today in the settling basins?

A. In my answer to your question as has already been practically stated in my statement that I would not recommend it as an absolutely safe water.

12793 Q. I am not asking, Doctor, for absolute safety.

Mr. Jeffries: Object to the question for the reason that the questions themselves put to the witness by counsel when the term safe is used it means and can mean nothing else except absolutely safe, unless counsel will put those questions so as to refer to particular conditions rather than absolutely safe conditions.

Mr. Todd: In reply will state that counsel for defendants believes that in the employment of the English language in expressing his questions that he needs no assistance on that point from my opponents.

Mr. Todd: Q. Doctor, would you recommend any river water in this country as a safe drinking water for drinking and domestic purposes, without filtering?

A. Replying to your question and assuming that by safe you mean absolutely safe, I shall have to say that I suppose that there is no river which flows over the surface which might 12794 not at some time become infected and that therefore under that assumption I could not recommend them in this country. There are many mountain streams which have been used for long periods with no ill effects to the persons using them as far as typhoid fever is concerned.

Q. Doctor, do you regard water that has gone through filters as absolutely safe?

A. I have already answered that question in the statement that there is no water flowing over the surface that might not receive some contamination.

Q. If you were called upon to recomend a water supply of a city, could you guarantee the water supply as being absolutely safe or can you conceive of a water supply as being absolutely safe, in the sense that you use absolutely?

A. I can conceive of a water being absolutely safe, but it is so difficult to find a large quantity of water that is absolutely safe that I should not expect to be able to recommend any supply of water in a large community that would be absolutely safe.

12795 Q. Would you recommend the water of any large river that receives the sewage of cities and the drainage from rural populations to any given community without filtration?

A. Oh, I might recommend under certain conditions other methods of purification than filtration.

Q. But eliminating the other methods, in its raw state, I mean would you recommend the water of any river east of the Alleghanies and within the Mississippi River valley as a safe drinking water, without filtration?

A. Yes sir.

Q. What rivers have you in mind?

A. I can not mention especial rivers because I have not examined any group of rivers with reference to that point, but I can conceive there are in the mountainous districts and in the region you have mentioned small rivers which are so remote from liability to sewage infection that they might be used.

Q. Would you recommend any river in this country that
received the sewage of any cities above it as well as the
12796 sewage from the rural and urban population as a safe
water supply for a city without filtration?

A. Under certain conditions there might be other methods of purification which could be substituted for filtration, I would say that I could not recommend a water such as you have described without some other process of filtration.

Q. What other process would you recommend?

A. Under certain conditions the process of purification by subsidence might accomplish satisfactory results.

Q. How long a period of subsidence would you recommend before the water would be reasonably safe?

A. That would depend upon the character of the water.

Q. Have you in mind any river in the Mississippi River Valley that you would recommend subsidence for a period of from three to five days as sufficient to make the water safe?

A. In reply to that question I shall have to refer again
12797 to our original discussion as to the Missouri River water.

Q. Have you ever been called upon to pass judgment upon the quality of a river water for drinking and domestic purposes when you recommended subsidence?

A. No sir.

Q. Have you ever been called upon to pass judgment upon the quality of a river water in its raw state for any municipalities in this country?

A. I have had occasion to give advice on such matters.

Q. Have you ever recommended for municipalities the use of river water without filtering?

A. No sir.

Q. Have you ever installed a filtration plant?

A. No sir, that does not come within the line of chemistry or bacteriology.

Q. Have you ever operated a filtration plant?

A. I have never operated one in the sense of having charge of the works. I have, of course, made analysis showing the character of the work.

12798 Q. Have you had anything to do with the engineering features of a filtration plant?

A. No sir.

Q. Have you ever accepted bids for the installation of a filtration plant or passed upon the reasonableness of the bills?

A. I have never been called upon to pass upon such matters when they are engineering matters.

Q. Have you ever employed men to operate a filtration plant and passed upon the reasonableness of their compensation?

A. I have never been called upon to make such decisions, no sir.

Q. Are you acquainted with what it cost to operate a filtration plant filtering 200,000,000 of gallons of water per day?

A. In a general way I know the cost of filtering water but it differs under different conditions, and as I give little or no attention to the engineering side, I have not paid special attention to that. 12799

Q. Have you had any experience in filtration plants in the Mississippi River Valley?

A. No sir.

Q. Are you acquainted with the number of men necessary to operate a filtration plant?

A. Why, in a general way I am.

Q. Is that information based upon actual experience in the employment of men figuring out the cost of the filtration plant?

A. No, sir, that has to do with the administration and engineering features of which I have had no experience.

Q. If you have had no experience in the engineering and administration whatever of a filtration plant, wherein does the element of cost come in, in operating a filtration plant when infection is present in the water, together with matters in suspension that are to be removed?

A. The chief sanitary object of filtering water is to remove the infection. The questions relating to the rapidity of 12800 filtration, the character of the filtration, the scientific oversight of the operation of the filter all depends upon the relative contamination of the water which has to be filtered.

In other words a water which has a certain or given contamination would be satisfactorily filtered at a certain rate. If the water had a greater amount of contamination then the rate, in order to accomplish the removal of the obnoxious parts, with the same degree of thoroughness, must be as a bacteriological factor slower and it will take a larger plant to filter the same amount of highly contaminated water than it would of a less contaminated water.

Then, further, as filters are liable to fail in their operations at times, a filter which is filtering water highly contaminated must have more careful scientific oversight in the way of the testings of the water to get at the general character of the water.

Q. Is it not a fact that the chief cost in the establishment and operation of a filter depends upon the matter in suspension and the question of infection is a matter of secondary 12801 consideration?

A. Not from a sanitary standpoint, no sir.

Q. What city in this country is operating the largest filter plant?

A. The plant which is operated in part in Philadelphia is one of the largest plants in the country, I believe.

Q. Do you know whether the waters of the Schuylkill and the Delaware rivers are any less infected than the waters of the Mississippi as they pass St. Louis?

A. The typhoid death rates of the two cities are both pretty high. The typhoid death rate at Philadelphia is higher than the typhoid death rate at present in St. Louis and from that standpoint I should judge that the water which is used in the raw state supplied in Philadelphia is a more contaminated water than that which has been supplied to St. Louis.

This opinion, however, is modified somewhat by the fact that part of the water in St. Louis is purified to a certain extent by the assistance of subsidence and part of the water
12802 supplied to Philadelphia is treated by filtration, so I cannot answer your question absolutely as to the relative contamination of the two streams. It is a question which I have not given special attention to.

Q. Are you aware, Doctor, that in the construction of filters in the city of Philadelphia, which is under the direction of John W. Hill, a bacteriologist and chemist and sanitary expert, that the question of infection is not an element of cost either in the building or in the operation of that filter plant, and that the chief cost is in the removing of the matters in suspension?

A. I am not aware of the figures in the case, no sir.

Q. Have you ever given the question consideration as to the difference in cost between a water that is sewage polluted greatly charged with matters in suspension and a water of equal pollution that has infection present as to difference in cost of operation and maintenance of a filtration?

A. As stated those are matters which pertain to the engineering side of the problem, and I have not given the details of such matter attention.

12803 Q. Then, Doctor, how were you able, in your examination, to pass an opinion as to the relative cost of filtration here in St. Louis with the waters of the drainage canal turned in over conditions that obtain if the sewage of Chicago was eliminated?

A. The opinion which I expressed regarding that was a general one in regard to the relation and not a specific one which would require the knowledge of an engineer and was based upon the considerations which I enumerated a short time ago relating to the question of rapidity of flow through the filters as affecting their size and the oversight as affecting the character of the effect from a sanitary standpoint, and I did not mean to express it on any other facts.

Q. The opinion then was very general?

A. It was general that it would cost more on these accounts.

Q. Have you any specific knowledge that justifies you in expressing such general opinion based upon your experience in matters of filtration and filter plants?

A. I know that it is customary in connection with the filter plants of the various cities in Europe to operate them ac-
12804 cording to the results of the bacteriological examinations. If the tests show a larger proportion of bacteria on a given day that is taken as evidence that the filter is passing the water too rapidly for a satisfactory purification, and then the rate is modified accordingly and this varies with the number of organisms in the raw water to be filtered.

Q. Doctor, have you made any experiments yourself upon the longevity of the typhoid bacilli?

A. No sir, not laboratory experiments.

Q. Have you made any experiments under natural conditions of the typhoid bacilli to ascertain its longevity?

A. Those would be what I would call laboratory experiments. I have not. I do not mean to say that it is in connection with laboratory methods.

Q. You stated that you were not acquainted with any experiments that limited the longevity of the typhoid to less than six days, outside of Jordan, Russell and Zeit. Do you mean to have it understood that there are no bacteriologists of a
12805 reputable standing that hold to the view that typhoid fever germs will not live to exceed six days in a sewage polluted water, or that you do not know of them?

A. What I meant to say was that I do not know of any one who would express an opinion to that effect as to the longevity of typhoid bacteria under natural conditions of sewage pollution of streams.

Q. Are you acquainted with the series of experiments conducted by John W. Hill in the laboratory at Philadelphia in sewage water for the purpose of ascertaining the longevity of the typhoid bacillus as affected by the chlorine in the water?

A. In a general way I know something of his work.

Q. Do you know what the results of those experiments were?

A. I know that the period was a short one, but I can not state the exact length of it. I do not know the exact date nor do I understand that as a result of those experiments the experimentors would be willing to apply those figures to 12806 sewage under natural conditions.

Q. Do you know that the result of those experiments did not extend the longevity of the typhoid bacillus six days?

A. I do not know that those experiments lead to the general conclusions which I have stated, that typhoid bacteria under natural conditions, as they exist in the sewage, do not have a longer longevity than six days.

Q. Are you aware of the fact that John W. Hill, who supervised those experiments testified in this case and gave his opinion that the typhoid germ would not live to exceed six days in diluted sewage?

Mr. Jeffries: Object to the question for the reason that the evidence of John W. Hill in this respect and to this effect based upon analyses as made by him and the analyses themselves were too limited to enable a sanitarian, to express an opinion as to the longevity of typhoid fever germs in sewage or in sewage polluted water.

Mr. Todd: In reply would state that notwithstanding counsel's objection John W. Hill did so express an opin- 12807 ion based upon the results of his examination.

A. That fact was called to my attention and was included in my answer when it was originally stated, outside of those who testified in this case—that was in the original question.

Mr. Todd: Q. Have you made any laboratory experiments upon the longevity of the typhoid bacilli in sewage, yourself?

A. As already stated, I have not.

Q. Then your opinion, as far as it is influenced by laboratory experiments, is influenced by the experiments made by others and not by yourself?

A. Assuming that my opinion was influenced by laboratory experiments or methods that would be so.

Q. Was your opinion influenced by laboratory methods?

A. The opinion that I expressed was that the laboratory experiments were so different from the conditions naturally occurring in sewage polluted streams, that in my opinion they were not adequate therefore I do not credit them as being sufficient to form a judgment on that matter and did not express an opinion. 12808

Q. You mean by that all the laboratory experiments of which you have knowledge?

A. Surely.

Q. Do you know of any experiments that have been made by any bacteriologist in this country or in Europe that simulates natural conditions as nearly as the experiments made by Professors Jordan, Zeit and Russell, to which you referred, and which were as extensive in their scope as that experiment upon the longevity of the typhoid bacilli?

A. No sir, I do not.

Q. Can you suggest any experiment that is possible to be made by a bacteriologist that would stimulate natural conditions more closely than the experiments made by Professors Jordan, Russell and Zeit on the longevity of the typhoid?

A. Yes sir; unquestionably the technique of such experiments could be rendered somewhat more approaching the natural conditions, but the problem is so difficult, the variations in the conditions are so extreme, the conditions that the typhoid bacillus exists in in the sewage is so different, that I can not conceive how laboratory conditions or methods can afford a perfectly satisfactory solution as to the matter of how long typhoid bacilli may exist in a stream, and in my opinion such data can not be expected to yield a definite, positive answer to that question under any given set of conditions. 12809

Q. Do you know how many distinct and separate experiments were made by these three experimentors on parchment sacs?

A. I looked over the list and I remember there were a considerable number.

Q. Do you know that they used in addition to the cultures bacteria the feces or urine of a typhoid fever patient?

A. Yes, I know that there was some variation in the details as to the source of the material.

Q. Will you state to what technique you refer that could supplement the technique that was employed in the making of these experiments? 12810

A. It would have obviated one difficulty if the sacs had been allowed to float down the stream, properly protected so that they would not have been subjected in succession to a series of different character of water as they must have been when they were put stationary at one point. That is one thing that would suggest itself to me.

Q. Any other?

A. These experiments might have been tried in sacs of such size as to admit the accumulation of considerable quantities of sediment with a view of ascertaining whether they would have influenced the result. That would have more nearly simulated the conditions in the stream.

Q. What criticisms have you of the celloidon sac method that was employed by Professor Zeit?

A. There is no particular criticism that occurs to my mind as comparing the use of the celloidon and the parchment. Of course there was a difference in the fact that one permits dialysis, while the celloidon does not. The experiments
12811 were very carefully worked out and unquestionably they
were very well done, but the difficulty of simulating natural conditions are what appear to me to be of importance.

Q. You have examined the typhoid fever statistics of the city of St. Louis have you not?

A. Yes sir.

Q. From what source did you gain your information as to the typhoid fever conditions in the city of St. Louis?

A. There were two sets of data brought to my attention. Those which have been referred to as the ones published in the reports of the Commissioner of Health and those which were referred to in my testimony of yesterday as having been furnished by Professor Sedgwick and Mr. Lochridge from the records in the mortuary office.

Q. Professor, do you regard intermittent, remittent, typho malaria, congestive and simple continued fevers as distinct types of disease?

12812 A. Under the names which you have described, there are different diseases included. The terms remittent fevers and intermittent fevers are names applied to a malarial infection and are in use in statistical work as representing the different manifestations of the malarial disease.

The term typho malaria is a term regarding which there is some variation in the usage in the medical profession. The best usage is that it should be confined to the condition which exists when there is in one person a combined infection of the typhoid and malarial organisms, but it has been used and is used by some practitioners as applied to malarial conditions which exhibit what is known as the typhoid state which refers rather to the symptomology than the cause, but it is not a typhoid infection, but it is the symptomatic condition which is best realized in the typhoid infection.

12813 The term congestive fever, by the best usage is undoubtedly restricted to a severe form of malarial infection which is manifested by the congestive chill.

The term simple continued fever is a term which is no longer correctly used and can not be used as representing any specific disorder but grouped under that have been unquestionably many low conditions which were characteristic or characterized by a continued fever. Many of these were simply bacterial infections but not associated necessarily with the typhoid organisms nor with the malarial organism.

Q. Are you acquainted with the mortality from malaria?

A. The mortality from malaria differs very greatly in different localities. In the temperate zones there is usually not much mortality to malarial diseases except among the feeble. This is of course seen more particularly among the feeble young and among the old, though of course adults of intermediate ages may succumb to malarial conditions if they are feeble.

12814 Then there are certain types of malarial disease such as typified by what I said concerning congestive fevers, which affect adults of all ages, but they are not very common in temperate zones. They are the malarial disease of the tropics.

Q. Do doctors confound typhoid fevers with other diseases?

A. Yes sir.

Q. And report deaths that should properly be typhoid under some other head?

A. Such confounding of diagnosis of course may happen. It is probably much more frequent among cases that do not die than among fatal cases because when a person dies from typhoid fever the condition is likely to display itself in such a character that the diagnosis is likely to be corrected at or before the time of death, if there was a mistake. There are some fatal cases that are misdiagnosed.

Q. In the number of deaths reported in the board of health
reports in the city of St. Louis under the heads intermittent, re-
mittent, typho-malaria, congestive and simple continued
12815 fevers, how many of those deaths would you charge to
malaria?

A. That is a question which I could not answer by any general average. The only way to answer such a question as that is to enquire into the habit of the office when these results are compiled and to state what the original diagnoses were.

Q. In your inquiry and investigation of the compilation of the mortuary office here, did you find a discrepancy between the figures in that office and those that are published in the official reports of the Commissioner of Health under remittent, intermittent, typho-malaria and congestive fevers?

A. There is a marked discrepancy between the list given in the report of the Commissioner and the data which were compiled by Professor Sedgwick and Mr. Lochridge from the records of the mortuary office.

Q. Did you make a comparison of the typhoid death rate as published with those that are in the same office, the number of typhoid deaths?

12816 A. The number of typhoids, yes. The two sets of records
substantially agree in this respect.

Q. Under the heading of intermittent, remittent, typho-malaria, congestive and simple continued fevers, what is your opinion as to whether any of those fevers should be properly classified as typhoid fever?

A. It is not uncommon to find differences in diagnosing in the early stages of typhoid fever and in mild cases between the malarial condition and the typhoid condition so that I think that errors of this sort are more or less common in the diagnosis of cases, but in the matter of deaths I can see no reason why there should be very much confusion, for the reason which I have already stated, that by the time a typhoid case reaches that condition where it proves fatal the disease has generally so directed itself so as to admit of the application of the diagnosis if there was an error.

There are, however, doubtless some cases which are never correctly diagnosed.

12817 Q. When a doctor, through his inability to diagnose a typhoid fever case as typhoid, treats it for something else and the patient dies, do you know of any case where he has subsequently changed his diagnosis and issued a death certificate after death?

A. Yes sir; the formal diagnosis is the diagnosis named on the death certificate, and the early diagnosis is very frequently a temporary one made in the family, and in many cases there is no statement made what the diagnosis is.

Q. But among the general practitioner when he treats a case for some other disease than that of typhoid fever and the patient dies, is there anything in the death of the patient that will inform that doctor that it is typhoid if he did not find it out before the death without a post mortem?

A. Not at the time of death because it is a condition which exists within a reasonable time prior to the death which reveals the true nature of the disease.

Q. Is it your opinion that the doctors in the general practice in a city like St. Louis are all qualified to diagnose ty-
12818 phoid fever, in all of its varieties?

A. I have no doubt that there are incompetent physicians in the city of St. Louis as there are incompetent persons in other professions or callings.

Q. Are you acquainted with the number of medical students turned out in the number of our western medical colleges in all schools of medicine in the Mississippi Valley each year?

A. I know that there are large numbers of medical students graduated in the western colleges and most of the colleges of this part of the country are now in what is known as the American Medical College Association, and they at present and for the past few years are having a very much stricter course than formerly, but that is true all over the country.

Q. In the certificates of death they are made up by doctors of all standing, high and low degree, are they not, that reach the health department?

A. Any registered physician may sign a death certificate, yes sir.

12819 Q. From your examination of the board of health in the city of St. Louis, did you find the accuracy in the comparing of statistics such as should obtain in a branch of government of such importance?

A. I have made no examination of the health office. The only matters that have come to my attention are the records of the Commissioner of Health and the data derived from the mortuary office. I know nothing about the details of the reports of the Commissioner of Health.

Q. In figuring out the typhoid condition in the city of St. Louis, did you allow any cases of typhoid fever under the column of remittent, intermittent, typho maiaria, congestive and simple continued fevers as being typhoid?

A. I have considered the typhoid deaths as reported, I have considered the data concerning each of the diseases which you have enumerated as well as those from malarial fever, and I have considered the statistics combining the typhoid
12820 deaths with those which are shown by those certificates
to be included in the miscellaneous class which you have enumerated.

Q. Did you allow any of the deaths reported under this miscellaneous class as typhoid in arriving at your conclusions as to the typhoid condition in St. Louis?

A. I have considered, as stated, that possibly, and I have seen, including them all in the typhoid deaths, there is still an increase of typhoid fever between the two periods, but I have further considered compilations of the deaths under each of the miscellaneous class, especially with the view of attempting to form an opinion as to whether any considerable portion of them might have been typhoid deaths. I can not state, of course, that none of them were, and I cannot state personally how many of them were, but considering them from the standpoint of the age of the persons and from the distribution of the cases of deaths by months, it will be seen that there would be comparatively few of those which are classified under 12821 this group which should be included in the typhoid class.

Q. Doctor, what effect would the coming in of a great number of people during the last three years, while the Exposition was being constructed here, and the number of people naturally attracted to St. Louis from people unacclimated, have upon the typhoid rate in the city of St. Louis?

A. The introduction into the city of a considerable number of persons from other sections might have some effect as raising the number of cases of typhoid fever.

Q. Was that fact taken into consideration by you in your testimony?

A. Yes sir.

Q. What proportion of typhoid deaths in the city of St. Louis would you attribute to local causes such as wells and the failure to remove garbage?

A. The number of cases which come from local infection such as wells is indicated to probably not have much 12822 more existed during the period since the opening of the canal than they obtained before the opening of the canal. There is, of course, no way in which I can estimate absolutely the proportion of the deaths which occurred during the years 1896 to 1899, inclusive, there is no way in which I could tell the proportion or portion from any such local cause and those which may be due to some other cause, but the rate which prevailed here during that time was about the same rate which we find in some of the better class of cities in this country.

RE-DIRECT EXAMINATION

By Mr. Jeffries:

Q. Doctor Smith, in reference to your testimony on cross-examination upon the longevity of the typhoid fever bacilli in a running stream, I will get you to state whether or not in your opinion the present state of bacteriology is such as to enable a sanitary expert to fix with accuracy the longevity of a typhoid fever bacillus in a running stream, under all conditions and at all possible times, and to state with even approximate 12823 accuracy the comparative resistance of a colon bacillus and the typhoid bacillus in a running stream under all possible conditions and at all possible times or to deduce from any experiments heretofore made and introduced as evidence in this case such true and trustworthy information as would enable you to conclude that a sewage polluted river might be used for drinking and other domestic purposes with absolute safety at all times and in all seasons?

Mr. Todd: I object to the question on the ground that I did not cross examine this witness upon the longevity of a typhoid bacillus in a running stream, and for the further reason that it is not re-direct examination of anything brought out in the cross, and for the additional reason not having been gone into on the cross it is not rebuttal evidence of anything offered in the case by the defendants, but it is a part of the original case of complainant and is therefore not rebuttal and consequently is incompetent, irrelevant and immaterial.

A. My reply to your question is a repetition of points which I have previously taken up, and I would therefore 12824 reply briefly that in my opinion the present state of bacteriology is not such as will permit an expert to fix with accuracy the longevity of the typhoid bacillus in a running stream under all conditions and at all possible times.

Further that it is not possible to state with accuracy the comparative resistance of the colon and typhoid bacilli in a running stream under all possible conditions and at all possible times, and further that it is my opinion the present state of bacteriology is such that it is not possible to conclude from bacteriological analysis that a sewage polluted stream might be so purified as to be used for drinking and other domestic purposes with absolute safety at all times and all seasons.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Doctor, what is the full length of the Connecticut River?

A. Why, it is about three hundred miles.

Q. What effect has a flood upon the water shed of the 12825 Des Plaines River and the upper Illinois River upon the sewage of Chicago coming through the canal during the time of such flood?

A. The effect of a flood at this point would be first to dilute the sewage and to hasten the period of passage of it through the river.

Q. State, Doctor, whether or not, under such flood conditions as mentioned in the last question, it would prolong the life of the typhoid bacilli and other pathgenic organisms?

Mr. Todd: I object to the question for the reason that it is not re-direct of any subject gone into in my cross examination, as I did not touch the question of the typhoid germ in the Illinois River for the reason that I have objected to its introduction into this case by this witness as being not rebuttal, and therefore on the theory that it is not re-direct of what I have gone into on the cross it is incompetent, and for the addition reason it is part of the original case of the complainant and should have been introduced in chief, and this is not the proper place to bring it in under the guise of rebuttal, and it is therefore incompetent, irrelevant and immaterial.

12826 A. The trend, as already stated, of bacteriology researches is to show that concentrated sewage has some deleterious effect upon the life of the typhoid bacilli, consequently the effect of diluting the sewage by floods in the upper Illinois river would be to introduce a condition which would tend to increase the longevity of the typhoid bacilli in the water, first by the dilution of the sewage itself and second by carrying the organisms quicker into the lower stretches of the river where there is more dilution from natural causes.

Mr. Todd: I move to strike out the answer for the reasons given in my objection to the question.

Mr. Jeffries: Q. Doctor, assuming that the total area of the Illinois River water shed is 32,081 square miles; that the total area of the Mississippi River water shed above St. Louis, Missouri, exclusive of the Illinois, is 1,396,170 square miles; assuming that the total drainage area of the Missouri River is 320,086 square miles; assuming that the total urban population, including the sanitary district of Chicago, upon the Illi-
12827 nois River is 1,843,800; that the total population upon the Missouri River is 552,000 from the mouth of said river to and including the city of Omaha; that the total population upon the Mississippi from Minneapolis is 697,200. Please state your opinion as to which of these rivers would be the more

unsafe and the more liable to contain dangerous disease producing organisms, basing your opinion upon your knowledge as a sanitarian and epidemiologist, and upon all of the chemical and bacteriological data that have been introduced in evidence in this case, and which you have observed, including the tables in Streams Examination, the health reports of the Board of Health of the State of Illinois, and the report of the University of the State of Illinois, and the tables and the experiments in reference to the colon and bacterial counts introduced in evidence by Professor Jordan, aside from those contained in the books just mentioned, including also the tables of results introduced in evidence as to the longevity of the typhoid germ in the parchment and celloidin sacs and the experiment of Doctors Zeit, Jordan and Russell?

12828 Mr. Todd: Object to the question for the reason that it is not re-direct of anything brought out in my cross-examination, and for the additional reason it is not rebuttal evidence of anything that is introduced in evidence by the defendants, but part of the original case of complainants and therefore incompetent, irrelevant and immaterial.

Mr. Jeffries: I suggest that this question is based upon the cross-examination given this witness by the counsel for the defendants.

A. I would state I have considered the data summarized in your question and would state it as my opinion that the water of the Illinois River would be most likely to contain the largest relative number of disease organisms such as are transmitted by sewage.

Mr. Todd: I move to strike out the answer for the same reason stated in my objection to the question.

Mr. Jeffries: Q. Based upon the same assumptions state whether or not it is your opinion that the Illinois River does or does not contain more disease producing organisms than
12829 either of the other two?

Mr. Todd: Object to the question for the same reasons stated in my objection to the previous question.

A. In my opinion the waters of the Illinois River do contain relatively more disease germs such as are transmitted by sewage than the waters of the other rivers mentioned.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. State whether or not that opinion applies to the condition of the water in the Illinois River at its mouth, the Mississippi River at a point immediately above Grafton, and the Missouri River at its mouth?

Mr. Todd: Object to the question for the reasons stated in my two previous objections.

A. In my opinion this does apply to the water at the mouth of the Illinois River as contrasted to the water at the mouth of the Missouri, in the Mississippi, in the immediate neighborhood at the points referred to.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

12830 Mr. Jeffries: Q. While it may be true that all river water should be filtered yet is it not essential to preserve the physical condition of the rivers in their natural state as near as may be?

A. It is my very positive opinion that it is desirable to preserve the rivers of our country as free from pollution by sewagic matter as possible, and especially as related to their use for drinking waters, and considering the question also of subsequent filtration.

Q. Is it not a fact, Doctor, that when filtration is undertaken that it is advisable to obtain that water for filtration, if obtainable, which has been the least subjected to sewagic discharges?

A. I will state it as my opinion positively that of two waters originally alike in other respects that one which has the least sewage pollution should be chosen for the process of filtration for a public drinking water supply.

Mr. Todd: Q. While it is desirable to preserve the rivers in their natural condition in your opinion does the State 12831 of Missouri, with the cities of Kansas City, Jefferson City, St. Charles and Cape Girardeau emptying their sewage into the Missouri and Mississippi Rivers present an exception in your opinion to the rule enunciated by you in answer to the former questions of Mr. Jeffries?

Mr. Jeffries: Object to the question for the first reason that we do not claim that any exception is necessary or made, and I object to the question for the further reason that there is no evidence showing that Missouri or any city, municipality or township that has ever taken sewage through a natural water shed and discharged that sewage into and upon a water shed other than that prepared by nature for it.

I object to the question for the further reason that the suggestions therein contained do not under any circumstances justify Chicago in the construction of the drainage canal and the discharge of the sewage from 2,000,000 of people into and upon the people residing in the Mississippi River Valley below the mouth of the Illinois River and compelling them to
12832 suffer the responsibilities of guarding against the destructive elements contained in such sewage when comingled by the action of the sanitary district of Chicago with the water used for domestic and drinking purposes in the Mississippi Valley and particularly in the State of Missouri and the City of St. Louis.

Mr. Todd: I move to strike out so much of counsel's address as is not included in the legal objection to the question.

Q. Question read.

A. Replying to your question I would say that we have to expect a certain contamination of the streams of a certain territory in which the population is growing, and while it is desirable to avoid that, we have got to endure the results of our own progress. I expect you would hardly think me qualified to express an opinion on a legal question as to whether water from another water shed could properly be brought into this water shed thereby increasing the pollution.

HERBERT E. SMITH.

ADJOURNED until 2:45 P. M., same day.

12833 2:45 p. m., Wednesday, May 25, 1904.
Room 282 Southern Hotel, St. Louis, Mo.

Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

JOHN W. ALVORD,

a witness called on behalf of the complainant, being duly sworn by the Commissioner, was examined in chief by Mr. Jeffries, and testified as follows:

Q. Please state your full name and address?

A. John W. Alvord.

Q. Also your occupation?

A. Sanitary and Hydraulic Engineer, Chicago, Illinois.

Q. How long have you been engaged in the practice of your profession as a hydraulic and sanitary engineer?

A. About twenty-four years.

Q. Where?

A. With Chicago as a center, in and about Chicago and the middle west.

Q. Mr. Alvord, give an outline in a general way of your educational training?

A. I was ready for entrance to the Sheffield Scientific
12834 School of Yale College in 1877, but was unable to take
the course owing to poor health. My engineering education has therefore been confined to study and travel, coupled with practical experience. The first engineering work in which I was engaged was in 1879 in Chicago in connection with the construction of the Hyde Park Pumping Station of the Chicago water works and the Inlet tunnel to such station under Lake Michigan.

Later, I was in charge of the operation of the Lake View Station of the Chicago water works, and was for four years City Engineer of Lake View, then a separate municipality from the city of Chicago, since annexed.

After the annexation of Lake View I engaged in general practice in sanitary work in the suburbs of Chicago and adjacent cities.

I visited Europe in 1888 and 1894 and examined the question of water purification and sewage disposal particularly. From 1890 to 1893 I had charge of a department in the construction of the World's Columbian Exposition at Chi-
12835 cago and in 1894 resumed private practice, since which
time I have been engaged in various capacities with

about thirty-five different city water works plants and about forty-five municipal sewer systems, including the purification of water supplies and the disposal of sewage. I was engaged in 1898 in making a report to the city of Columbus, Ohio, on the extension of its sewer system and the disposal of its sewage, which report was published.

From 1898 to 1902 I was consulting engineer to the Illinois State Canal Commission, advising as to the works of the sanitary district channel in and through Joliet and in the litigation as to the removal of dams and locks at Joliet.

I have been engaged recently in the development of water power at Petosky, Michigan, and Big River, Missouri, and Des Moines, Iowa. I have been engaged in the design of some twelve water works plants which have been constructed and in which the question of river pollution bore an active part.

I have had some limited experience in typhoid epidemics, having studied them at Hurley, Wisconsin; Iron Wood,
12836 Michigan, and Culver Academy, Indiana in 1894, and the
typhoid epidemic of Chicago in 1892 and 1893, the Duluth epidemic of 1896, the typhoid epidemic at Grand Forks, North Dakota, in 1894, and was engaged to investigate the causes of the epidemic at Wequetansing, Michigan, and Petosky, Michigan, in 1903.

Q. State whether or not the epidemics that you have referred to were caused by water in any case?

A. So far as I have studied them they were all caused by polluted water supplies.

Q. Are you familiar with the Chicago river, the drainage canal, the Desplaines and the Illinois river?

A. I am. In 1888 I was engaged in conducting the litigation in behalf of the State of Illinois with the Sanitary District, in the course of which the hydraulics of the upper portion of the Desplaines river were thoroughly reviewed. I have studied in general the progress of the construction of the drainage channel and the related questions, and I was engaged in working for the special commission which reported upon its com-
12837 pletion.

I have observed the Illinois river at Morris, Ill., where I designed the system of sewers; at Ottawa, where I was engaged in water power litigation; at Marseilles, where I advised as to the enlargement of the water power, and have also observed the general characteristics of the river at Seneca, La Salle, Peru, Hennepin, Peoria, Pekin and Havana, at which latter two places I have designed sewerage systems.

I am also familiar with the Mississippi river from St. Louis to Alton, to some extent.

Q. State whether or not you are familiar with the ordinary minimum flow of the Illinois river before and since the opening of the drainage canal?

A. I have had occasion to observe at different times before the opening of the drainage channel the flow of the Illinois and the lower Desplaines river, and have also observed it since the opening of the drainage channel.

Q. Mr. Alvord, state whether or not you have given the subject of bacteriology any attention in connection with your
12838 profession?

A. I have to a limited extent. I have tried to keep myself posted upon bacteriology in a general way ever since it has come into use among engineers.

Q. Now state whether or not you have familiarized yourself with the subject of chemistry as applied to your profession?

A. Also to a limited extent. I took a partial course in chemistry at the University of Chicago in 1894. In 1900 I studied bacterial quantitative analysis under the advice of Professor Novy of Ann Arbor, Michigan. I have endeavored to keep informed on the subject in everything which would be of interest to my work as a sanitary engineer.

Q. State whether or not you were ever engaged with the water investigations of the city of St. Louis?

A. I was employed in 1902 by the special commission that investigated the extension of the water supply of the city of St. Louis, and my part of the work was to study the financial history of the present works, their physical cost and the cost of their operation. In the course of this work I became familiar
12839 with the characteristics of these works and have visited
the Chain of Rocks stations and sedimentation basins, also the old station at Bissel's Point, and have studied the physical features of the sedimentation plant.

Q. State whether or not you have made any special study of the typhoid condition on the water shed of the river above St. Louis?

A. To some extent.

Q. Where did you obtain the data which you have in regard to the typhoid deaths and the population of these water sheds?

A. From the records in this case.

Q. From evidence introduced by the respondents?

A. Yes sir.

Q. And complainants?

A. Yes sir.

Q. State whether or not you have prepared a diagram showing the relations of typhoid fever deaths in St. Louis with typhoid deaths on the water sheds?

A. I have.

Q. Will you submit this diagram?

A. I will.

12840 MR. TODD: Objected to for the reason it is not rebuttal as part of the complainant's case, complainant's original case and gone into in chief, and is therefore incompetent, irrelevant and immaterial.

MR. JEFFRIES: I will state in answer to the objection that this diagram is based not only upon the evidence introduced by complainant as to the number of deaths upon the respective water sheds, but is also based upon the additional evidence in relation thereto by respondents.

MR. TODD: In reply would state that while complainants attempted to introduce the typhoid statistics of the cities on the three water sheds in their original case and did not introduce them all, that defendants supplemented that evidence by the additional cities not introduced by complainant, but that does not make this competent evidence on rebuttal as it is admitted by counsel in his statement that complainant went into the question of the typhoid fever statistics on the water sheds of the three rivers when putting on his case in chief, and is therefore incompetent, irrelevant and immaterial, and not rebuttal.

12841 MR. JEFFRIES: Q. I will ask you, Mr. Alvord, whether or not this diagram is based upon the typhoid fever deaths upon the water sheds of the Mississippi, the Illinois and the Missouri rivers respectfully, as shown by a tabulated sheet of the evidence upon that subject, introduced in this case?

MR. TODD: Object to the question for the same reasons stated in my previous objection.

A. It is.

MR. JEFFRIES: I now, Mr. Commissioner, offer this diagram in evidence.

MR. TODD: Objected to for the same reasons heretofore stated.

The diagram is as follows:

12842 Complainant's Rebuttal Chart No. 1.

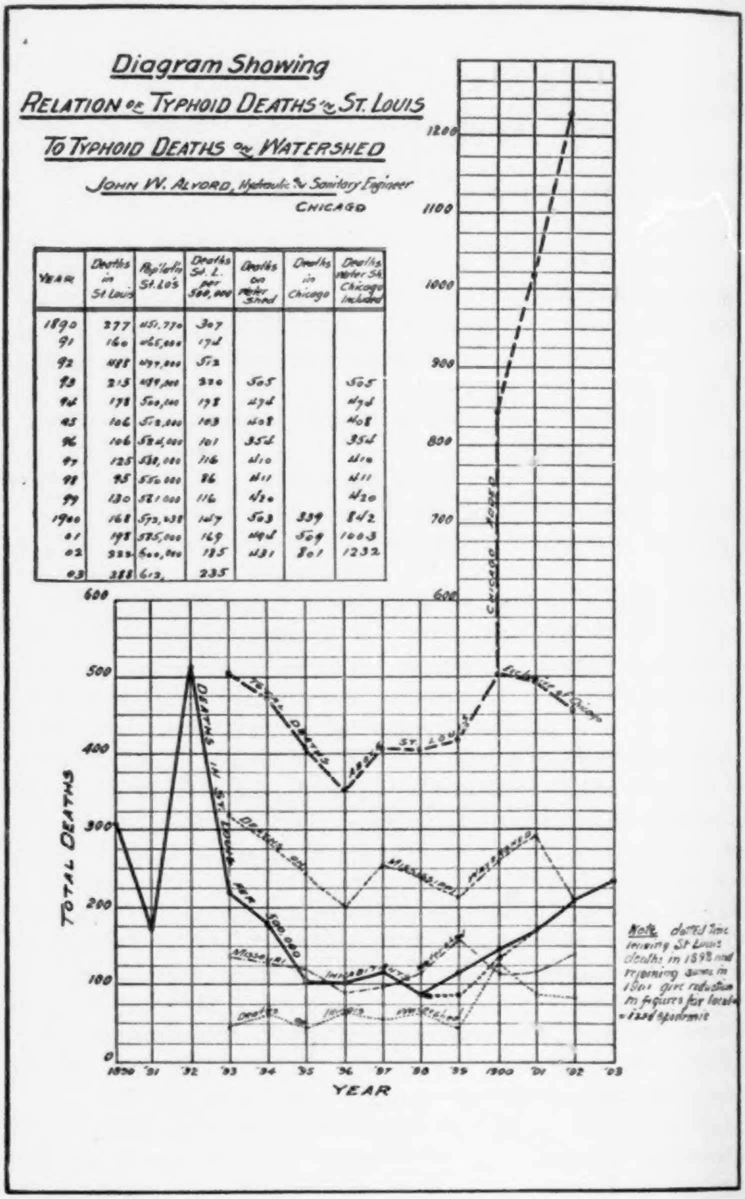

Diagram Showing
RELATION OF TYPHOID DEATHS IN ST. LOUIS
TO TYPHOID DEATHS ON WATERSHED

JOHN W. ALVORD, Hydraulic & Sanitary Engineer
CHICAGO

YEAR	Deaths in St Louis	Pop'lat'n St. Lo's	Deaths St. L. per 500,000	Deaths on Water Shed	Deaths in Chicago	Deaths Water Sh. Chicago Included

DEATHS IN ST. LOUIS PER 500,000 INHABITANTS
TOTAL DEATHS ABOVE ST. LOUIS
Exclusive of Chicago
CHICAGO ADDED
DEATHS ON MISSISSIPPI WATERSHED
MISSOURI
DEATHS ILLINOIS WATERSHED

12843 MR. TODD: I move to strike out the diagram for the same reasons stated in my objections heretofore made.

THE COMMISSIONER: This diagram is known in evidence as complainant's rebuttal chart number 1.

MR. TODD: I object to the word rebuttal and object to it being characterized as such.

MR. JEFFRIES: Q. Please explain this chart or diagram?

MR. TODD: Objected to for the reasons heretofore stated.

A. The data from which the diagram is plotted are shown in a table of seven columns, in the upper left hand corner. The first column which gives the year in which the deaths occurred, the second column showing the total typhoid deaths in St. Louis for each given year, the third column showing the population of St. Louis for each given year, taken from the Federal Census for the years 1890 and 1900, and the Federal estimated census for the years 1901 and 1902, and estimated complete for the remaining years, such estimate being made at the proportional rate of increase to the figures of the Federal census and the Federal estimates.

12844 The fourth column gives the typhoid death rate in St. Louis per 500,000 population, being reduced to that standard population for the years as given.

The fifth column gives the typhoid deaths on all of the water sheds above St. Louis, taken from the records in this case above referred to and excluding the sanitary district of Chicago.

The sixth column gives the typhoid death rate in the city of Chicago for the years 1900, 1901 and 1902, as taken from the record in this case above referred to, and the seventh column gives the death from typhoid for all of the water sheds above St. Louis, including the Sanitary District of Chicago, as taken from the records in this case above referred to.

The diagram is plotted so that the ordinates represent the total typhoid deaths, the abscissa the years from 1890 to 1902, inclusive, in which such deaths occurred. The lower dotted line of the diagram marked deaths on the Illinois water shed shows the deaths on the Illinois water shed, excluding the drainage district for the years 1893 to 1900, inclusive. Above this line will

be found a light dash and dotted line marked Missouri
12845 water shed, which gives the total typhoid deaths on the
Missouri water shed for the years 1895 to 1902, inclusive.

Above this line again will be found a light dash line marked deaths on the Mississippi water shed which gives the typhoid deaths on the Mississippi river above St. Louis for the years 1893 to 1902, inclusive.

Above this line again will be found a heavy dash line marked total deaths above St. Louis, exclusive of Chicago, which gives the total typhoid deaths on the three combined rivers above St. Louis for the years 1893 to 1902, inclusive, excluding the Sanitary District of Chicago.

In January, 1900, the drainage channel was opened, adding the discharge of the sanitary district of Chicago to the last described line. This is shown on the diagram by a line extending vertically upward from the last described line to the year 1900 and plotted of such a length so that it shows the total deaths from typhoid in that year in the sanitary district of Chicago which is added to the total typhoid deaths on all the water sheds.

This heavy dashed line, marked on the diagram "Chicago
12846 added," extends diagonally upward from the year 1900
through the years 1901 and 1902, being in each case plotted
so that the total typhoid deaths in the sanitary district of Chicago are added to the total deaths on the line marked total deaths above St. Louis, exclusive of Chicago, and shows the total deaths on all water sheds including the sanitary district of Chicago. The heavy line on the diagram marked "Deaths in St. Louis per 500,000 inhabitants," shows the typhoid deaths in St. Louis taken from the records in this case above referred to for the years 1890 to 1903, inclusive, the dotted line leaving this heavy black line in the year 1898 and rejoining it again in the year 1901 shows a correction made by deducting certain deaths due to a localized milk epidemic described by Professor Sedgwick and Mr. Lochridge.

MR. TODD: I move to strike out the answer for the reasons given in my objection to the question.

MR. JEFFRIES: Q. Mr. Alvord, state what conclusions you draw from this diagram?

MR. TODD: Objected to for the reasons heretofore
12847 stated.

A. It has been the endeavor in this diagram to disclose the causes for the increase in typhoid deaths in St. Louis during the last few years. In order to intelligently determine such causes, the typhoid deaths along the different rivers have been separated from each other and platted separately so as to determine the source of the most marked pollution. It will be seen that the deaths from typhoid on the Illinois water shed, exclusive of the sanitary district of Chicago, are fairly uniform up to the year 1899, but show a rise in the year 1900, the year in which the drainage canal was opened. Otherwise they seem to be fairly uniform for the years preceding and following the commencement in the rise in the number of typhoid deaths in St. Louis.

The deaths on the Missouri river water shed appear also to be reasonably uniform for the period under consideration, and the typhoid deaths on the Mississippi river water shed, while fluctuating somewhat more than the first two described, are nevertheless generally uniform before and near the rise in the typhoid deaths in St. Louis.

In summing up the total typhoid deaths on the water shed
above St. Louis, as given in the record, it would appear
12848 that while there is some fluctuations and a low period
about the year 1896 that at no time since the rise in
tphoid deaths in St. Louis they have materially exceeded a fair
average rate and have in fact fallen off since the year 1900.

It will be observed, however, that the addition of the deaths from the sanitary district almost doubles the total typhoid deaths, influencing the pollution of the St. Louis water supply and that such addition is materially increased during the years 1901 and 1902, so that in 1902 the total typhoid deaths are nearly two and one-half times the deaths on the water shed above St. Louis, exclusive of the sanitary district of Chicago.

A local epidemic in St. Louis typhoid deaths in 1892 is clearly shown by the diagram and is attributable to the contamination of the water supply at the old station at Bissell, by Ginras Creek, and neighboring sewers.

Upon the removal of the source of supply from Bissell's Point to the chain of rocks in the years 1894 to 1895 there is shown a marked improvement in the total number of deaths from typhoid for the latter year.

12849 MR. TODD: I move to strike out the answer for the reasons given in my objection to the question.

MR. JEFFRIES: Q. What cities were considered by you on the three water sheds in the plotting of this diagram?

A. Only those referred to in the records of this case.

Q. I will ask you to state briefly, if you know, what changes have taken place in the conditions of the water in the Mississippi river at St. Louis since the removal of the intake from Bissell's Point to the chain of rocks in 1895?

MR. TODD: Object to the question for the same reasons heretofore stated.

A. The sanitary district of Chicago opened their channel on or about the 17th of January, 1900, introducing into the water shed above St. Louis a large additional amount of water and sewage.

MR. TODD: I move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. State whether or not you are acquainted with the physical conditions, drainage area and the population upon the water sheds of the Illinois, the Mississippi above Grafton and the Missouri river. 12850

A. In a general way I am.

Q. Taking into consideration the evidence introduced in this case upon the typhoid death statistics upon the water sheds of these rivers, and all evidence in connection therewith, I will ask you to state to what do you attribute the increase in typhoid in the city of St. Louis, during the years 1900 to 1903, inclusive?

MR. TODD: Object to the question for the reason it is not rebuttal and part of complainant's original case and it is not proper to go into the original case under the pretext of rebuttal and is therefore incompetent, irrelevant and immaterial.

Q. Question read.

A. I should consider, after a study of the data that in all human probability the rise in typhoid deaths in the city of St. Louis in the last few years has been caused by the added typhoid contamination from the sanitary district of Chicago.

12851 MR. TODD: I move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. In what way, Mr. Alvord, is the longevity and vitality of typhoid organisms of special interest to you in your profession as a sanitary engineer?

MR. TODD: I object to the question as immaterial.

A. In advising municipalities as to the purity and safety of their sources of water supply.

Q. State whether or not you are familiar with and have acquainted yourself with the literature upon this subject?

A. I have endeavored to do so for the past fifteen or eighteen years.

Q. What was your object in doing so?

A. In order that my advice to municipalities might be conservative.

Q. What do you consider in your practice and in the recommendations which you make in your profession as a fair statement of the longevity of typhoid organisms which would lead you to give what you consider conservative advice upon this subject?

MR. TODD: Object to the question as not rebuttal and 12852 therefore improper, incompetent, irrelevant and immaterial.

A. I have for some years past considered the life of the typhoid bacilli would be from sixty to ninety days under favorable environments, and while large masses of such bacilli might be removed from any given source of supply in a comparatively short time under unfavorable environments, it would not be safe to assume that a water once thus polluted would be safe to recommend for public use under the time given, unless the contamination were eliminated by a carefully designed and properly operated system of purification.

MR. TODD: Move to strike out the answer for the reason given in my objection to the question.

MR. JEFFRIES: Q. Are you familiar with the results of the experiments found in the reports of the Massachusetts Board of Health in which Hiram T. Mills presents data on the longevity of typhoid bacilli in the waters of the Merrimack river which results were obtained by him upon analysis and experiments conducted by him?

A. I am.

12853 Q. Where, if any, do you find other similar experiments or determinations?

MR. TODD: Object to any other experiments being introduced for the reason it is not proper rebuttal and not referred to by defendants in putting in their evidence, and it is therefore incompetent, irrelevant and immaterial and not proper evidence.

A There will be found in the proceedings of the Sanitary Institute of 1899, some experiments made by Dr. Horrocks which appear to be similar to those carried out by Mr. Mills. These experiments are also quoted in Mr. Samuel Rideal's book on sewage, on page 70.

MR. TODD: I move to strike out the answer for the reasons given in my objection to the question.

MR. TODD: Q. Are the experiments that you are quoting the experiments of Mills?

A. No sir, Horrocks.

MR. JEFFRIES: Q. Are you familiar with the sewerage system of Chicago?

A. I am. A portion of it has been constructed under
12854 my design and supervision.

Q. Under what conditions in your opinion are typhoid bacilli carried away from Chicago so as to approximate conditions which Mr. Hiram F. Mills and Dr. Horrocks used in their experimental work?

MR. TODD: Object to the question as not proper rebuttal.

A. The sewerage system of Chicago has very flat gradients and requires frequent artificial flushing. It has been the history of heavy rainfalls in that city that the entire content of the sewers are at such times disgorded into the river bringing into it a mass of pollution which has been accumulating for months together. Before the opening of the drainage channel such periods were extremely dangerous to the water supply of the city, as was shown in the increase in typhoid deaths following the period of such contamination. Such heavy flushings of rainfall occur
ordinarily in the early spring or after the breaking up of
12855 the winter and at times when the temperature is most
favorable to the longevity of the typhoid germ and greatly increases for the time being the rate of pollution in the drainage canal and Desplaines and Illinois rivers.

In my opinion the action of such a flushing of the Chicago sewer system into the Chicago river with its present large proportion of pure water and low temperature furnishes conditions which parallel or indeed form more favorable conditions to the longevity of pathogenic bacteria than those under which the experimental work above noted were taken. The discharge of this various amount of pollution at times of flood waters appears also to furnish the necessary velocity for rapid conveyance through the drainage canal down the Desplaines and Illinois rivers to the intake of the St. Louis water supply; the increment of tributary streams also increases the dilution and decreases the chance for toxic destruction of the total number of typhoid germs present. Such conditions are prevalent in greater or less degree during many times of each spring.

MR. TODD: I move to strike out the answer for the
12856 reasons given in the objection to the question.

MR. JEFFRIES: Q. In what you have said of the spring flood, do you have reference to the ordinary spring floods or to the exceptional floods which sometimes occur in this region?

MR. TODD: Object to the question for the same reasons heretofore given.

A. My answer refers entirely to ordinary conditions such as occur perhaps eight or ten times or more in the spring of each year and often at other times in the year, rather than to exceptional floods since as that of 1888 or 1892 and one or two other heavy floods in which extreme high water marks were reached. Such floods would naturally produce the danger from typhoid pollution to greater distances from the source or origin.

MR. TODD: I move to strike out the answer for the reasons given in the objection to the question.

MR. JEFFRIES: Q. Are there any other evidences from the testimony introduced in this case and which you have observed which would increase the flow above that men-
12857 tioned by you?

A. Yes sir, in the case of heavy rainfall on the water shed of the Chicago river, it is often necessary in order to prevent outflow into Lake Michigan through the main river, to lower the Bear Trap Dam at Lockport so as to produce greater velocity at all stations down the channel at such times. This undoubtedly aids in the rapidity with which pollution is conveyed away from Chicago down the channel of the Desplaines and Illinois rivers.

Q. What are the conditions of stream flow in the Desplaines river?

MR. TODD: I object to the question for the reason that the whole question of streams flow and the Desplaines river was gone into in chief by Professer Teichmann and consequently is not rebuttal testimony and therefore incompetent, irrelevant and immaterial.

A. Below the outlet of the drainage canal at Lockport, the Desplaines river flows very rapidly to a pool formed by what is known as dam number one at Joliet. This descent over ordinary and normal flow produces rapid velocity and
12858 a slight rise, but rainfall will develop velocity in the channel of from 40 to 60 miles per day.

MR. TODD: Move to strike out the answer for the reasons given in the objection.

MR. JEFFRIES: Q. What are the conditions of flow in the Desplaines and Illinois river as far down as the Marseilles dam?

A. Below dam number one and at Joliet the flow again becomes very rapid at times of moderate rises. This flow is slightly checked through Lake Joliet, but there is a further rapidity incurred on its outlet all the way down to the mouth of the Kankakee river. Below this point the Marseilles dam slightly checks the current.

Q. What are the conditions of flow in the Illinois river immediately below the Marseilles dam, below Marseilles at Peru?

A. Another rapid flow takes place below the Marseilles dam as far down as to Peru, where the influence of the Henry dam is felt.

Q. State whether or not that is especially true in time of
12859 spring floods or rises?

A. In the time of spring rises the velocity in these reaches is very materially increased, running, as I have said, up to as high as forty to sixty miles a day.

Q. Are you familiar with the testimony of Mr. Randolph in this case?

A. I have read Mr. Randolph's testimony.

Q. Taking into consideration the testimony of Mr. Randolph and the testimony of all other witnesses affecting the subject of hydraulics and sanitary engineering, I will ask you to state, Mr. Alvord, what effect, if any, has the discharge of 250,000 cubic feet of water per minute through the Chicago Drainage Canal upon the dangerous and deleterious substances contained in the sewage discharged into the Chicago river and the drainage canal?

MR. TODD: Object to the question for the reason it is not rebuttal of anything offered by the defendants, but is a matter that was gone into by complainant in his original case
12860 and it is therefore incompetent, irrelevant and immaterial.

A. The effect is to materially increase the current of the Desplaines and Illinois river and to carry dangerous pollution to greater distances and with more rapidity.

MR. TODD: I move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. Are you familiar with the flow measurements of the Chicago river, the main drainage canal, the Desplaines river and the Illinois river as described by Mr. Randolph in his testimony?

A. I have studied them.

Q. Do you know the discharge of the river at the time these observations were made under Mr. Randolph's directions?

A. I am unable to find anything in Mr. Randolph's testimony which gives any clue to the amount of discharge in the Desplaines and Illinois river either at Joliet or Peoria and therefore am unable to determine what stage the river was in at the time of his float measurements. The times of these experiments were in July, 1903, as appears by the record and such time is not covered by the table of discharge given in his testimony at Lockport, nor are any guage readings given at
12861 Peoria where the testimony includes a rating table. I only find the statement that the floats passed over this distance in fifteen days, which is raised to eighteen and one-half days by dividing by eight-tenths.

Q. What distance do you refer to in your last answer?

A. The distance from the Chicago river to the chain of rocks in the Mississippi above St. Louis.

Q. As a hydraulic engineer state whether or not the time limit as ascertained by the floats should be raised in the manner indicated by Mr. Randolph in his testimony, by dividing by .8?

A. I fail to see the pertinency of his conclusion that a correction should be made, tending to reduce the maximum surface velocity to the mean velocity of flow. The use of the .8 correction, in the manner described in Mr. Randolph's testimony is a very rough approximation, used by hydraulic engineers when surface floats are run in the most rapid part of the channel of a river to determine the average flow for the whole cross section of the channel in order to get at the
12862 quantity passing a given point per second. In the case under consideration, we are not endeavoring to determine the quantity of water passing any given cross section per second, but the problem presented is what length of time will any given pollution, flowing in mid channel, pass over the necessary distance from the Chicago river to the chain of rocks. This only requires, in my opinion, a determination of the mean velocity of the bore or central section of the stream.

Q. Do you as a hydraulic engineer consider the floats described by Mr. Randolph and Mr. Crane as surface floats?

A. I should not consider them so. As described in the testimony they appear to be partially submerged and I believe they give the mean velocity of the central portion of the stream with a fair degree of accuracy.

Q. Assuming, Mr. Alvord, that these determinations as made by Mr. Randolph give the mean velocity of the central portion of the stream, state whether or not in your opinion corrections of the character named and described by Mr.
12863 Randolph are necessary?

A. I believe that they are not necessary.

Q. What, then, would you consider the length of time that it would take pollution to pass over the described distance as the results of these experiments so conducted by Mr. Randolph at the time such experiments were made?

A. I should judge that fifteen days actual time would fairly represent the ability of the water of the Illinois and Desplaines rivers to carry pollution to the Chain of Rocks at the stage when the experiments were made.

Q. State whether or not in your opinion the mean flow of the stream should be considered as the time element in the passage of sewage and pollution from a given point to a point below on that stream?

A. I think it should not. Pollution is carried much faster on a given stream than would be indicated by a mean average flow. It may not be carried as fast as the very fastest thread of the stream, but it is certainly carried as fast as the average velocity of the central or fastest part.

12864 Q. Have you examined the evidence of the experiments conducted by Professor Van Ornum, described in the records of this case?

A. I have.

Q. Taking into consideration the testimony of Mr. Randolph in the experiment which he conducted with the floats in obtaining the velocity of the water in the Illinois river, in July, 1903, I will ask you to state what conclusions you draw from a comparison of the respective velocities obtained by Mr. Randolph and Professor Van Ornum, and taking into consideration the evidence as to the guage readings that existed for a period prior to these experiments and subsequent thereto, as introduced in evidence by Mr. Randolph and Crane, in what way do these experiments represent the minimum or maximum velocity of the water in the Illinois river?

MR. TODD: I object to the question for the reason it is not competent for this witness to draw conclusions based upon the testimony of Randolph or Van Ornum as it is a matter for the court, and for the further reason that the question of velocity in the Illinois river is a matter that was gone into in chief by complainant in his original case with Professor Van
12865 Ornum and is not proper rebuttal and therefore is incompetent, irrelevant and immaterial.

A. I should judge, in answer to the first part of your question, that the float experiments of Mr. Randolph in July 1903, were undertaken at a very much lower stage of the river than were those of Professor Van Ornum in March, 1903, as Professor Van Ornum finds materially greater velocity than does Mr. Randolph.

I also observe that Professor Van Ornum commenced his float experiments in a low stage point, between two March rises, in the river. There were flowing over the Bear Trap dam at the time he commenced his operations, as taken from the figures in the tables in the evidence, 289,000 cubic feet per minute, which gives a rather low velocity in the drainage channel. About 394,000 cubic feet per minute was passing over dam number one at Joliet at the same time.

Eight days prior to this, and on the 8th and 9th of March, 707,000 and 718,000 cubic feet per minute, respectively, passed over the dam at Joliet.

12866 Five days after Professor Van Ornum commenced his experiments, or on the 21st and 22nd of March, 764,000 and 711,000 cubic feet per minute passed over dam number one, or nearly double the amount of flow, both earlier and later, was in existence than occurred when his experiments were commenced.

It would seem, therefore, that Professor Van Ornum's experiments were undertaken at a very comparatively high stage but not by any means the highest stage so far as the drainage channel and the upper portion of the Desplaines river are concerned.

In passing Peoria, Professor Van Ornum observes the stage of water upon the gauge, which I find, by referring to the table of flow submitted by Mr. Jacob A. Harmon, in this case, gives a flow of about 50,000 cubic feet per second. This flow would correspond to a stage of the river which is somewhat overflowing the banks in the lower courses.

As Professor Ornum used submerged floats, I feel that the actual time traveled by the velocity floats represents fairly the mean velocity of the pollution vehicle, and I take the total time as represented by these floats as representing the total
12867 time which it requires to travel the total distance under consideration, with the exception that I believe that there are times when the velocity in the drainage channel in that portion of the river immediately below the Bear Trap Dam is greater than those which he found.

In 1898 I was engaged as consulting engineer for the State Board of Canal Commissioners in litigation with the sanitary district of Chicago over certain water powers and these channels below the Bear Trap Dam, and had occasion to very carefully study the velocities and stages and various stages in this vicinity. I have, therefore, verified Professor Van Ornum's float experiments in this vicinity, recognizing them to correspond with what I know to be the facts in the spring rises in the upper portion of the course under consideration. Below Lake Joliet I have accepted Professor Van Ornum's experiments to the chain of rocks as being properly indicative of what might happen in ordinary spring floods.

From Bridgeport to the chain of rocks I find that 9.8 days is consumed, using mean velocity to Joliet, and Professor Van Ornum's float experiments from there to the chain of
12868 rocks. I do not consider that this is the shortest time in which polution would travel this distance, but believe that the maximum flood such as occurred in 1892 would reduce this time to at least eight days and possibly slightly less. The 9.8 days represents to my mind a stage which could be counted upon as occurring a number of times in each year.

MR. TODD: I move to strike out the answer for the reasons given in my objection to the quetsion.

MR. JEFFRIES: Q. State whether or not you have had occasion to examine and study the velocity and stages of the rivers in question, in the course of your professional career?

A. I have.

Q. From what you have said of your observations of the testimony introduced in this case and of the testimony of Mr. Randolph, from his float experiments, state whether or not in your opinion the float experiments of Mr. Randolph represent a minumum velocity of the water in the Illinois river from Chicago to St. Louis at all times of the year?

MR. TODD: Object to the question for the reasons it is not competent for this witness to pass judgment upon the
12869 testimony of another witness and on the additional ground that it is not rebuttal as the question of the float experiments was entered into in complainant's case in chief and this testimony is not rebuttal and is therefore incompetent, irrelevant and immaterial.

A. Not having been able to ascertain the specific stage at the time of Mr. Randolph's experiments, I should be unable to state positively that his experiment was made at the minimum stage of the river, but speaking generally it is my impression that it was and represents the average of the minimum velocity in the ordinary dry seasons of the year between the Chicago river and the chain of rocks.

MR. TODD: I move to strike out the answer for the reasons given in my objection to the question.

MR. JEFFRIES: Q. I will ask you if you have examined the chart referred to by Mr. Rudolph Hering, 12870 who testified for respondents in this case, in which it is referred to by Mr. Hering in his evidence as follows, the chart with the caption "Sanitary District of Chicago, schematic representation of the self-purification of the waters of the Missouri, Mississippi and Illinois rivers between the points indicated based upon the longevity of the life of the typhoid bacillus as fixed by the experiments made under the direction of Hiram F. Mills, the results of which are given in the paper entitled 'Typhoid fever in its relation to water supply?' "

A. I have.

Q. State what to you, then, it represents, as observed by you as a hydraulic sanitary engineer?

A. It represents an attempt to derive the possible amount of contamination in the water at the chain of rocks from the sanitary district of Chicago, by assuming that the original pollution is proportional to the population, and that the longevity of a typhoid bacillus is, as found by the experiments of Hiram F. Mills in the paper referred to. The chart also makes the same deductions for the Mississippi and Missouri rivers and gives the rate of fall of the three watersheds. In the case of the Illinois river the length of time of flow from the Chi- 12871 cago river to the chain of rocks is taken at 18½ days, as stated by Mr. Randolph from his experiments, after adding to the original experiments an additional time for the correction to the mean velocity. It would seem to me in the first place that Mr. Hering has not given due weight to the relative effectiveness of different populations in the production of typhoid pollution. The sanitary district of Chicago has been afflicted for years with an abnormal number of typhoid deaths. Other cities on the Illinois watershed, deriving their water supply from artesian wells, have extremely low death rates from the same cause. It would appear, therefore, to me, that to make the diagram more exact some method should be introduced by which the disparity in typhoid data could be allowed for in its effect upon the St. Louis water supply.

Again, I should judge that the diagram as compiled under Mr. Hering's direction gives the time of travel of the pollution vehicle at low stages of the river and therefore does not 12872 fairly indicate the greater danger of pollution to the St. Louis supply at medium or high stages of the river. It would seem that the diagram should be so constructed that these modifications might be clearly apparent.

Q. Have you prepared a diagram which, according to the methods suggested by Mr. Hering, based upon the experiments of Mr. Hiram F. Mills, which would also include the two modifications just described by you?

A. I have.

Q. Will you submit this diagram?

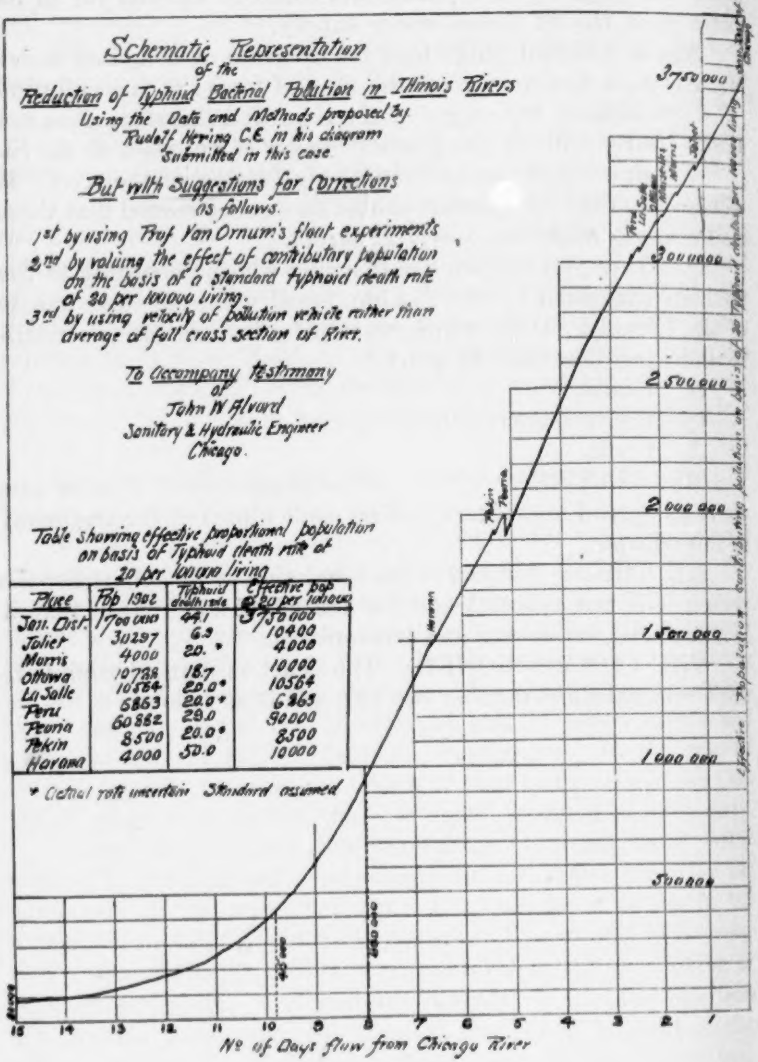
A. I will.

MR. JEFFRIES: Now, Mr. Commissioner, I offer this chart to be read in evidence and be made a part of the testimony of this witness.

MR. TODD: I object to the admission of this chart for the reason it is not rebuttal and for the additional reason that it is immaterial, irrelevant and incompetent.

THE COMMISSIONER: The chart is marked complainant's rebuttal chart number two (2), and is as follows:

12873 Complaints Rebuttal Chart No. 2.



Schematic Representation of the Reduction of Typhoid Bacterial Pollution in Illinois Rivers

Using the Data and Methods proposed by Rudolf Hering C.E. in his diagram submitted in this case

But with Suggestions for Corrections as follows.

1st by using Prof Van Ornum's float experiments

2nd by valuing the effect of contributary population on the basis of a standard typhoid death rate of 20 per 100000 living.

3rd by using velocity of pollution vehicle rather than average of full cross section of River.

To accompany testimony of John W Alvord
Sanitary & Hydraulic Engineer
Chicago.

Table showing effective proportional population on basis of Typhoid death rate of 20 per 100000 living

Place	Pop 1902	Typhoid death rate	Effective pop @ 20 per 100000

No of Days flow from Chicago River
Effective Population contributing pollution on basis of 20 Typhoid deaths per 100000 living

12874 MR. JEFFRIES: Q. Will you please explain this diagram or chart?

MR. TODD: Objected to for the reasons stated in my objection to its admissibility.

A. The diagram which I have submitted covers only the reduction of the typhoid bacterial pollution in the Illinois river as being the object under consideration, and is prepared as nearly as possible in the manner described by Mr. Crane in his testimony, using the experiments of Mr. Hiram F. Mills as to the longevity of the typhoid germ. The ordinates in the diagram represent the tributary population calculated in its relative typhoid death production. As a basis for this I have assumed a standard of 20 deaths per 100,000 living as being the death rate of an ordinary well regulated city in the situation of Chicago, having due regard to the protection of its water supply.

Upon this basis I have determined for the year 1902 the typhoid death rate of Chicago and the cities along the
12875 Illinois river which are given in the table in the lower left hand corner of the diagram.

This diagram shows in the first column the place under consideration; in the second column the population of the place from the estimated Federal census of 1902, when possible. The third column shows the typhoid death rate in 1902 per 100,000 living, and the last column shows the tributary population contributing typhoid contamination on the basis of 20 deaths per 100,000 living, per annum, as calculated from the actual population and the actual typhoid death rate. The population of the sanitary district is taken from Mr. Hering's chart and not from the Federal census. The abscisse of the diagram give the number of days consumed in the flowing of the pollution from the sewers of Chicago to the 15th day, based upon the float experiments of Professor Van Ornum, from Lake Joliet to the chain of rocks, and from my estimates of the velocity in the drainage canal, and Desplaines river down to Lake Peoria.

12876 With this data I have plotted a curve in a similar manner to that plotted upon the diagram prepared under the direction of Mr. Hering, giving due consideration to the percentage of reduction in the typhoid contamination from the population center through the proper increments of time to agree with the experiments of Hiram F. Mills.

MR. TODD: I move to strike out the answer for the reasons given in my objection to the question.

MR. JEFFRIES: Q. State what the curve in this chart indicates?

MR. TODD: Object to the question for the same reasons heretofore stated.

A. The curve plotted upon the diagram indicates the relative typhoid bacterial pollution, so far as the same can be predicated upon the population, by using the bacterial reduction found in the experiments of Hiram F. Mills and substantiated by Dr. Horrocks.

MR. TODD: I move to strike out the answer for the reasons heretofore stated.

12877 MR. JEFFRIES: Q. State whether or not as a general proposition the number of deaths from typhoid fever in any community represent the total amount of pollution from typhoid bacteria?

MR. TODD: Object to the question for the same reasons heretofore stated.

A. They do not; if they are confined to deaths only they do not represent the whole number of cases.

MR. JEFFRIES: Q. What else should be taken into consideration?

MR. TODD: Object to the question for the reasons heretofore stated.

A. There are always a very large number of cases of typhoid fever which recover and which nevertheless are active producers of typhoid infection in addition to the infection produced by cases when deaths have occurred.

Adjourned until May 26, 1904, 10:00 a. m.

12878 Room 282, Southern Hotel, St. Louis, Mo. 10:00 a. m., Thursday, May 26, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

JOHN W. ALVORD

resumed the stand for further direct examination, by Mr. Jeffries, and testified as follows:

Q. State whether or not this diagram, as constructed, represents pollution from fatal cases alone or from all cases which actually existed in the communities under consideration, special reference being here made to complainant's rebuttal chart number two (2).

MR. TODD: Object to the question for the reasons heretofore stated, as not rebuttal.

A. It represents the comparative pollution contributed by the fatal cases alone. Furthermore it should be remembered that fatal cass cease to contribute infection to the stream 12879 on and after the date of the death, while unfatal cases do and may continue to contribute infecting material to the stream for days, weeks and even months.

The diagram as constructed fails to take account of this extra and added pollution and is therefore conservative.

MR. TODD: I move to strike out the answer for the reasons heretofore stated, and that part of the answer wherein the witness attempts to describe the conservativeness of the diagram as the diagram speaks for itself and it is a matter for the Court to de [illegible] tness to characterize.

MR. JEFFRIES: Q. How do the corrections which you have applied to Mr. Hering's chart affect the final results and especially the estimate of the typhoid contributing pollution at the chain of rocks?

A. Assuming active typhoid contamination is proportional to the population, and assuming diminution in the number of typhoid germs day by day to be as shown in the experiments of Mr. Hiram F. Mills, the modifications which I have introduced in the diagram would considerably increase the 12880 amount of typhoid pollution entering the intake at St. Louis.

I find that whereas Mr. Hering's diagram shows that the typhoid pollution entering the intake at the chain of rocks is equivalent at the end of a low river flow of 18½ days to an infection from a tributary population immediately above the intake of a city of 13,000 people, the conclusions of the diagram would seem to indicate that the normal flow of fifteen days would be equivalent to an infection from a tributary population with a death rate of 20 per 100,000 living of a city located immediately above the intake, with a population of about 90,000 people, while on the basis of ordinary spring floods, such as were gauged by Professor Van Ornum the infection arising at the chain of rocks would be equivalent to the population of a city of 415,000 population, situated immediately above the intake tower, and with a typhoid death rate of 20 per 100,000.

With a maximum flood such as occurs only once in every
several years, it would appear that the comparative
12881 pollution reaching the intake of the St. Louis water-
works would be equivalent to a population of 960,000
with a typhoid fever death rate of 20 per 100,000 living, this latter assumption being based upon the movement of the pollution vehicle from the Chicago river to the chain of rocks in eight days.

MR. TODD: I move to strike out the answer for the reason it is not rebuttal, in this that it takes into consideration elements which are based upon the assumption of the witness himself and not upon any facts that are proven in evidence as based upon a typical typhoid basis which the witness himself presumes to assert as a maxim which is not proven in evidence by any other witness and which was not considered in Rudolph Hering's chart, and is therefore new matter and not proper rebuttal and consequently is incompetent, irrelevant and immaterial, and for the further reason that the charts and conclusions drawn therefrom do not make any comparison between conditions of the Mississippi and Missouri river as the chart which Hering introduced in evidence did and is therefore not rebuttal in any way.

12882 MR. JEFFRIES: Q. Why do you employ 20 deaths
from typhoid fever per 100,000 population in your last
answer?

MR. TODD: Object to the question for the reasons heretofore stated that it is not rebuttal.

A. Because there are a very considerable number of cities which have so exercised care and discretion in the protection of their water supplies that they have reduced the typhoid death rate to a point below this rate. Some of the smaller cities upon the Illinois river have typhoid death rates as low as 6.9 per 100,000 living. It would therefore seem to be a fairly reasonable standard to assume that all cities having reasonable regard to the purity of their water supplies should be able in the light of present science to reduce their typhoid death rate at least to the basis assumed, if not materially lower.

MR. JEFFRIES: Q. In the chart which you have introduced in evidence in comparison with the chart or diagram introduced in evidence by Mr. Hering, based upon the experiment of Hiram F. Mills, what weight do you attach to these
12883 experiments?

A. I believe they are what might be termed incomplete investigations, that is to say, they are valuable, but neither sufficiently comprehensive nor numerous. The results show that typhoid germs do live under the conditions of the experiments the length of time given, but they do not show that typhoid germs may not live much longer. The difficulty of isolating typhoid bacteria from waters of known pollution would seem to substantiate this view of

MR. TODD: I move to strike out the answer for the reason that this witness by his qualifications has not shown sufficient bacteriological knowledge to be an authority upon criticising the extent to which he refers of Hiram F. Mills and for the additional reason that it is not rebuttal of any testimony put in the case by the defendants as the experiment of Hiram F. Mills was introduced in evidence by complainant on his own original case and quoted in support of that theory of the case, and it is incompetent for complainant to rebut the testimony of his own witnesses.

12884 MR. JEFFRIES: Q. Are you familiar with the testimony of Professor Kinnicutt in this case?

A. I have read it over.

Q. State whether or not you are familiar with the principles of practice of modern sewage purification?

A. I am.

Q. State whether or not you have given attention to the development of processes of sewage purification by means of septic tanks?

A. I have given particular attention to the development of septic tanks and have designed some ten or fifteen plants for muincipalities in which a septic tank has been employed on my recommendations. Of these plants eight septic tanks have been constructed under my immediate supervision for different municipalities and have been in operation for periods ranging from one to four years. Two of these plants have been under my immediate supervision ever since construction and I have watched the operation of others.

Q. What is septic action and how long should sewage remain in a septic tank in order to obtain practical results from a sanitary standpoint?

12885 MR. TODD: Object to the question for the reason it is not rebuttal as the question of septic tanks was gone into in chief in the testimony of Dr. Ravold and made a part of complainant's original case.

A. Septic action is the process of breaking down the organic matters in sewage by micro-organisms or their products in the absence of oxygen. This process is continuously brought about by allowing the sewage to come nearly or quite to a state of rest in deep tanks and allowing it to remain so until the dissolved oxygen present, if any, is exhausted and until the solid particles of the sewage have been attacked and broken up more or less in soluble compounds. It is desirable in order to provide favorable conditions for this process that the temperature remain as constant as possible and very high, and it is preferable that light and air should be excluded, although this is not absolutely essential. The proper period of rest necessary to get the best results will vary with the composition of the sewage, its temperature and character. It has been found desirable to adjust the rest period so that the temperature and 12886 other variables can be controlled and the period of rest adapted to the concentration of the sewage and its relative flow proportioned to the tank in which it is confined.

MR. TODD: I move to strike out the answer for the reasons given in the objection to the quetsion.

MR. JEFFRIES: Q. State whether or not flowing sewage ordinarily undergoes the process of septic action?

A. It does not ordinarily.

Q. State whether or not diluted sewage flowing in open channels simulate septic tank conditions?

A. It would not. The flow of liquids through open channels tend to bring all portions of the liquid from time to time to the surface where it may receive oxidizing influences tending to retard septic action.

Q. Are you acquainted with the present physical condition of the Chicago Drainage Canal?

A. I am.

Q. Please compare the conditions existing in the Chicago Drainage Canal with those of a true septic tank?

12887 A. In the Chicago Drainage Canal we have a large volume of diluted sewage flowing at the rate of one to three feet per second, giving ample opportunity for renewing its dissolved oxygen. And we have this action further increased by the opportunity of the wind to stir the surface of the stream and still further oxygenate it.

We have also an opportunity for exposure to low temperatures, light, etc., which are detrimental to the septic action.

Q. State whether or not septic action to any considerable extent takes place in the sewage of Chicago during its passage through the drainage canal?

A. It does not.

Q. Are you acquainted with the chemical data that has been introduced in evidence by the defendants?

A. I am to some extent.

Q. State whether or not in your opinion the chemical data introduced by the defendants with reference to the character of the contents of the Chicago drainage canal, indicate any septic action has taken place?

12888 A. My opinion is that they do not. The amount of improvement in the sewage in its travel of the drainage canal found by Professor Kinnicutt in his testimony in this case would seem to me to be largely due to aerobic action. Possibly there is anaerobic action to a very limited extent, but not enough in my opinion to influence the results perceptibly.

Q. State whether or not the extensive dilution of the sewage of the city of Chicago by the richly oxygenated water of Lake Michigan is a useful preliminary to septic action?

A. It is not. On the contrary it is distinctly opposed to the inception of septic action. In good practice, in the designing of septic tanks it is the endeavor always to bring the sewage into the tank as quietly as possible, undiluted with surface or underground waters containing undissolved oxygen.

Q. State whether or not you were familiar with the South branch of the Chicago river prior to the opening of the drainage canal?

A. I am.

Q. What was the condition of that part of the river at that time?

A. It presented all the characteristics of septic action to a marked degree.

12889 Q. What were those characteristics?

Mr. Todd: Object to the question for the reason that the characteristics of the South branch of the Chicago River were gone into in chief by Professor Ravold and this is not rebuttal evidence of anything that has been put in by the defense and is not contradictory of any testimony, and a part of complainant's original case and therefore incompetent, irrelevant and immaterial.

A. The absence of marked current, and the presence in certain places of more foul products and considerable surface scum, the absence of undissolved oxygen as shown by chemical examinations and the visible production of gases bubbling up from the depths below such as characterize the septic tank when in active reduction of its organic matter.

MR. TODD: I move to strike out the answer for the reason stated in my objection to the question.

MR. JEFFRIES: Q. State whether or not in your opinion typhoid germs are now more able to survive longer under the present condition of sewage dilution in the drainage 12890 canal than they could formerly have survived in the South Branch of the Chicago River or in the Illinois and Michigan Canal?

Mr. Todd: Object to the question for the reason that this matter was gone into in chief by the complainant in the testimony of nearly every witness who testified to any knowledge of the South Branch of the Chicago River, and it is not rebuttal testimony and therefore incompetent, irrelevant and immaterial.

A. I believe that typhoid germs could survive materially longer under the present conditions than was the case formerly in the Illinois and Michigan Canal and the South Branch of the Chicago River.

Mr. Jeffries: Q. Taking into consideration your knowledge of septic operation, and all that you know upon the subject of sanitary science and sanitary hydraulic engineering and taking into consideration the physical condition of the Illinois River the drainage canal and the Desplaines River, and the chart or diagram introduced in evidence by Mr. Hering, and the diagram introduced in evidence by you in connection therewith, state whether or not in your opinion the presence
12891 of sewage from the sanitary district of Chicago in the waters of the Mississippi River at the chain of rocks makes it more costly to provide suitable water for domestic purposes for the citizens of St. Louis?

Mr. Todd: Object to the question for the reason that it is part of complainant's original case, and the subject matter of the question was gone into in detail by every witness who took the stand for complainant and is therefore not proper rebuttal and consequently is incompetent, irrelevant and immaterial.

A. In my opinion it does make it more costly.

Mr. Todd: I move to strike out the answer for the reasons given in my answer to the question.

Mr. Jeffries: Q. In what respects is the water supply of St. Louis made more costly or difficult by virtue of the opening of the drainage canal?

Mr. Todd: Object to the question for the reasons stated in my objection to the previous question.

A. The design and construction of a purification plant dealing with a seriously polluted water, especially of one of known high typhoid pollution should be more complete and delicately adjusted to its work than when dealing only with water
12892 of rare infection and presenting less dangerous difficulties such as turbidity and color.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. What form should this added protection take?

Mr. Todd: Object to the question for the reasons heretofore stated in my previous objections.

A. It should take the form either of double filtration or have complete sedimentation in more than one stage followed by most careful filtration.

Mr. Todd: I move to strike out the answer for the reasons stated.

Mr. Jeffries: Q. State whether or not you know of any case where double filtration is being used or resorted to?

Mr. Todd: Object to the question as the matter of double filtration has been gone into in complainant's case in chief by Mr. George W. Fuller and is therefore not rebuttal of anything offered by the defendants.

12893 A. It has been resorted to in several places in Germany and has been recommended at Springfield, Massachusetts, by Messrs. George W. Fuller and Samuel M. Gray, and is now being introduced into the new filtration plant of Philadelphia by Mr. John W. Hill, in which case they are proposing to pass water of known typhoid pollution through what are called preliminary filters as a first stage and then through slow sand filters as a second stage.

Mr. Todd: I move to strike out the answer for the reasons stated.

Mr. Jeffries: Q. Would such methods be more expensive than single filtration?

Mr. Todd: Object to the question for the reasons heretofore given.

A. They would. It is my opinion that they would very greatly increase the cost of filtration, both in its first construction and in operation.

Mr. Todd: I move to strike out the answer for the reasons stated.

Mr. Jeffries: Q. State whether or not single sand filtration as practiced in the United States is always a protection from the danger of typhoid infection?

12894 Mr. Todd: Object to the question for the reasons heretofore stated, that it is not rebuttal.

A. It is not.

Mr. Todd: **I move to strike out the answer for the same** reasons.

Mr. Jeffries: **Q. Why is it not?**

Mr. Todd: **Objected to for the reasons heretofore stated.**

A. **Sand filtration of either type is practically able to remove** pathogenic **bacteria from domestic water supply, but we** find that in **practice filtration works are a most delicate mechanism,** which **have to be very carefully operated in order to produce** at all **times and under all conditions the results antici**pated by their **designers. In cases where the danger of infec**tion hovers **over the filtration plant year in and year out it is** obvious that **the slightest relaxation may result in the most** serious **consequences.**

Mr. Todd: **I move to strike out the answer for the reasons** stated in **the objection to the question.**

Mr. Jeffries: **Q. State whether or not you know from your** own observations **and study of the cases in which single sand** filtration **or filter plants of either type have failed to**
12895 protect **the water supplies from typhoid infection?**

Mr. Todd: **Object to the question for the reasons here**tofore stated.

A. I do. **There have come under my observation, typhoid** epidemics in **water supplies protected by filtration in the follow**ing places:

Rock **Island, Illinois,**
Ashland, **Wisconsin,**
Berlin, **Germany,**
Lawrence, **Massachusetts,**
Lake **Forest, Illinois,**
Butler, **Pennsylvania,**
Waterloo, **Iowa,**
Beaver **Falls, Pennsylvania, and**
Augusta, **Maine.**

MR. TODD: **I move to strike out the answer for the rea**sons stated **in the objection to the quetsion.**

MR. JEFFRIES **Q. Mr. Alvord, are you a member of any** engineering **societies or associations?**

A. Yes, **sir; I am a member of the American Associa-**

12896 tion of Civil Engineers since 1893. I am a member and trustee of the Western Society of Civil Engineers. I am president of the Illinois Society of Civil Engineers and Surveyors. I am a member of the American Waterworks Association and of the New England Waterworks Association. I am also a member of the American Public Health Association, and am serving this year upon its committee of water and sewage purification. I am a member of the American Association of Municipal Improvements of the American Academy of Social and Political Science, and of the Engineers' Club of Chicago.

Q. Mr. Hering, who testified for the defendants on March 10th last, was asked by counsel for the defendants the following question "From what you know of the question of disposal of sewage and from the knowledge which you have in regard to the drainage canal, the manner in which it is operated, and taking into consideration the experience you have had since you made your preliminary report, what changes would you recommend for the sewage disposal of the city of Chicago if the same problem was submitted to you now which was submitted to you in 1886, as a sanitary and hydraulic engineer?" Answering this question Mr. Hering said that in considering the several ways of disposing of the sewage of Chicago, from personal knowledge and experience, my recomendation would be that the sewage of Chicago should be disposed of by dilution through the channel substantially as that which has been constructed with the subsequent discharge into the Desplaines and Illinois rivers." Thereupon the following further question was asked him: "In the study of this problem have you discovered anything that would change the view expressed by you in your preliminary report at that time?" In answer to which question Mr. Hering said: "I have not." I will ask you, Mr. Alvord, to state whether or not there are in your opinion any practical modifications of the existing system of sewage disposal of the city of Chicago by which the drainage canal could still be employed for keeping the Chicago river in an inoffensive condition and yet avoid the pouring of unpurified sewage into and through the canal over the Bear Trap Dam at Lockport and into the Desplaines and Illinois rivers? 12897

MR. TODD: Object to the question for the reason that it
is incompetent, irrelevant and immaterial and for the
12898 further reason that it is not for the complainants to de-
vise means for the disposal of Chicago sewage unless
the only complaint that complainant may have is whether the flowing of the sewage is a danger and a menace to the public health of the citizens of Missouri using the water for drinking and domestic purposes, and is therefore incompetent, irrelevant and immaterial.

A. I am of the opinion that it is entirely practicable to retain the drainage channel so that it can be still employed for keeping the Chicago River in condition and yet avoid pouring unpurified sewage into and through the canal and into the Desplaines and Illinois Rivers, and I would suggest as the proper remedy the construction of suitable intercepting sewers along the Chicago River and its branches, by means of which the sewage flow of the city may be kept out of the Chicago River and lead along its banks to the upper end of the drainage channel beyond Bridgeport and then raised by a suitable pumping station preferably operated with water power derived from the drainage canal to and into a suitable purification plant con-
structed in accordance with the latest bacteriological
12899 principles and effectually remove from such sewage all
or practically all of its organic wastes and pathogenic
bacteria and emptying the effluent from such sewage plant into the drainage channel near Bridgeport to be conveyed through the same and through the Desplaines and the Illinois Rivers in a harmless and purified state.

Mr. Todd: I move to strike out the answers for the reasons given in the objections to the question.

Mr. Jeffries: Q. State whether or not you have considered the relative expense of such a plant as you have described in your last answer?

Mr. Todd: Object to the question as immaterial and not proper rebuttal.

A. I have considered the expense in a general way and am of the opinion that such intercepting sewers and purification plant could be constructed at an expense no greater than that necessary to widen the South Branch of the Chicago River in order to increase its flow of dilution water to the requirements of dilution.

And I am further of the opinion that the operating ex-
12900 pense of such a plant would be no greater than the operating expense of the present system of pumping sewage and the necessary dilution water through the same for the northerly and southerly portions of the sanitary district and the dilution water for the proposed additions to such sanitary district.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

CROSS-EXAMINATION, by Mr. Todd:

Q. In figuring out such a purification plant as you have referred to in your last answer and the building of intercepting sewers and the operation of pumps and the installation of pumping machinery, what estimate in dollars and cents do you place that such a plant would cost, according to your estimates?

A. Between twelve and fifteen millions of dollars.

Q. Does that contemplate the purification of the entire sewage of the sanitary district?

A. It does.

Q. From Calumet on the south and Lake View on the
12901 north and the building of intercepting sewers on each side of the Chicago River and on each side of the north branch which receives the sewage from its adjacent neighborhoods as well as the sewage from Twelfth Street south and the west side?

A. I should not think it necessary to build intercepting sewers on each side of the river. One main sewer connecting across the river by tunnels would probably result in economy of expenditure over a double intercepting sewer along each bank.

Q. How would you intercept the sewers that empty into the Chicago River from its left bank?

A. I should carry an intercepting sewer along either one or the other banks of the river, along the most economical location, connecting it with the mouths of the sewers on each side of the river, either by short branch tunnels, grouping several sewers together on the opposite side or in the case of the large sewers by direct tunnel connections in each case.

Q. What would be the cost that you would figure for the pumps necessary to pump the entire sewage of Chicage from its sewers and the intercepting sewers to this purification plant?

A. I would not be able to give you those detail figures at this time as I do not have them by me. The estimates were made some years ago.

12902 Q. How many acres of land would be necessary for the plant located in the neighborhood of Bridgeport, sufficient to dispose of the entire sewage of the city of Chicago and the sanitary district?

A. That would depend entirely upon which of several available systems of bacterial purification might be adopted.

Q. Taking the one that you had in mind when you gave your testimony?

A. I do not think I had any particular one in mind.

Q. How were you able to make an estimate if you did not have a particular system in mind upon which to base an estimate?

A. By estimating the cost of the one which would in all probability be the least and the most expensive.

Q. Taking the one that would probably be the most expensive, how many acres of land in the neighborhood of Bridgeport would it require to establish such a purification plant?

A. Possibly 1,000 acres.

Q. Do you know what the value of real estate in the neighborhood of Bridgeport is?

12903 A. I have general ideas.

Q. What are your ideas on the value of 1,000 acres of land in the neighborhood of Bridgeport where you contemplated the establishment of such a plant, per acre?

A. Possibly a half a million of dollars. It would be desirable perhaps to place the plant at the point where the maximum of land could be obtained at the minimum price, not confining ourselves to any exact location in the vicinity or below Bridgeport.

Q. Have you any spot in mind where such an amount of land could be had near Bridgeport at $500.00 per acre?

A. The sanitary district of Chicago has a large amount of land in that vicinity and without having given the subject particular attention I should judge that it might be possible that they had land enough without having to purchase any additional.

Q. Do you assert that as a fact or as a surmise that the sanitary district owns 1,000 acres of land within a distance of three or four miles of Bridgeport, available for such use?

A. I would not limit myself to three or four miles. It is not necessary in the location of such a plant to limit
12904 yourself. The plant could be eight or ten miles away.

Q. If the sanitary district of Chicago owns 400 feet on each side of the channel from its mouth at Robey Street to Summit, with the exception of a few places where it goes back as far as 700 or 800 feet, would you consider the plant such as you have contemplated could be utilized on a long stretch of that kind?

A. It might be done or some other mode of purification which occupied less land than that, which I have estimated might be put in. There are several different kinds of bacteriological purification which demand different and varying amounts of land. We find at times we are limited in land and we recommend often that kind of purification which can be placed upon the minimum of land. If we find that land of a suitable character exists in abundance it varies our ideas as to what form of purification we would recommend.

Q. In bringing the sewage from the different sections of the city what estimate did you place upon the cost of the construction of additional sewers in order to bring the sewage to the plant?

12905 A. About five million dollars.

Q. Where would those sewers be located?

A. Following as closely as possible the north and south branches of the Chicago river and endeavoring to strike with the shortest possible length the greatest number of present sewer outlets emptying into the river.

Q. Have you figured out the cost of such a system as you have in mind in making your estimate?

A. I have figured it far enough to see that it is practicable and reasonably economical.

Q. Will you give in detail briefly the plan which you have in mind for the disposal of Chicago sewage?

A. Well, I have quite a number of plans in mind. I have not limited myself to any one plan.

Q. Well, give me the plan as it pertains to the delivery of sewage to the plant which you had in mind?

A. Well, in order to utilize as far as possible construction already commenced, I would begin by saying that the intercepting sewers now under way would form possibly a basis for conducting the sewage of the outlying portions of the city
12906 from the north end and from the south districts so far
as they go. These I should supplement with additional intercepting sewers conveying their conduits and the outflow of the sewers now emptying into the different branches of the river to the vicinity of the drainage channel beyond Bridgeport, necessarily finding that in doing so I had consumed some gradient or fall which must be recovered by pumping not only to raise the sewage to the level of the drainage channel, but to raise it an additional height necessary to pass it through that system of purification that might be selected. Different systems of purification also vary in that they require different amounts of head necessary to properly purify the sewage which passes through them.

Q. How would you bring the sewage from the north branch of the city to Bridgeport?

A. The north side of the city has already under construction a system of intercepting sewers along the lake shore now completed, and a branch across at Lawrence Avenue to the north branch of the Chicago river where it is proposed to erect a pumping station to elevate that sewage into the north branch. This collects all of the sewage of the north portion of the city,
which formerly emptied into the lake. I would, there-
12907 fore begin at the point where this sewage is to be lifted
into the north branch and continue a new intercepting sewer from that point along the north branch of the Chicago

River on the side which might be found by detailed study to be the most convenient, thence to the junction of the north branch with the south branch of the Chicago River and along the south branch of the Chicago River to Bridgeport, in such location that it would receive the discharge of all of the sewers on the north side of the city not connected with the intercepting sewer system now under construction, it would be further necessary in order to collect the sewage of the north side of the city to extend a short branch of the intercepting sewer easterly from the junction of the north and south branches of the Chicago River to intercept those sewers emptying into the main river from the north side.

Q. How would you bring the Calumet District to Bridgeport?

A. The Calumet district within the limits of the sanitary district is now proposed to be brought to the east fork of the south branch by a system of intercepting sewers now nearly completed. This intercepting system contemplates a pumping station in the vicinity of Seventy-third Street, I think,
12908 proposals for which have just recently been advertised.
This pumping station will lift the sewage of the extreme southern portion of the district into the intercepting sewer already finished or nearly so which runs northerly along Stoney Island Avenue and the right of way of the Illinois Central Railroad to Thirty-ninth Street, where a very large pumping station is now being erected to pump dilution water into a conduit which will take such dilution water and sewage from the intercepting sewer and carry it westerly to what is known as the Stock Yards Slip at Halstead Street.

Q. How would you take the sewage from South Chicago by the method you have described as the method adopted for the Calumet District?

A. The sewage of South Chicago is proposed by the present plans of the sanitary district of Chicago to be carried to the main channel by way of Blue Island and the Sag Valley. I would say that in making my estimate of $5,000,000.00 for intercepting sewers I covered the territory of the original sanitary district and not the district as enlarged by the act of the Legislature in 1903. Such outlying territories as have since

been added could be brought to Bridgeport in any event by methods and at an expense which would be equal in
12909 either case with the methods and within the costs now proposed by the sanitary trustees, but the preference, if any, in favor of the system which I have outlined is that no dilution water would have to be pumped in addition to the sewage.

Q. What estimate do you place for the widening and deepening of the Chicago River to a width of 200 feet and to a depth of 26 feet, as is contemplated to be done at present?

A. The best of my knowledge and belief the estimates for widening of the Chicago River to the uniform width of 200 feet so far as I have seen them published range from eleven to fourteen million of dollars. I believe it would be fair to say that the cost can not be accurately estimated in advance as large portions of valuable land will have to be acquired by condemnation.

Q. Are you aware of the amount of land that has already been acquired by condemnation?

A. I am aware that condemnation is constantly going on.

Q. Are you aware that over seven-tenths of the land has already been acquired?

A. I have no information other than that that I have stated.

Q. And this is in detail the method of the sewage disposal systems that you have proposed to construct, the amount of land that it would be necessary to acquire under this
12910 estimate is in the neighborhood of twelve million dollars?

A. The total cost of the whole project would be twelve to fourteen millions of dollars.

Q. At the time that Mr. Hering made the preliminary report when the question of sewage disposal for Chicago was under consideration was the question of bacteriology then recognized as a science?

A. Not generally.

Q. Was the question of the purification of sewage in the manner that you have described it then known?

A. The purification of sewage was then known and extensively practiced, but the systems which I now have in mind were not developed, and speaking generally the systems then in use while efficient, were expensive.

Q. What experiments have you conducted upon the longevity of the typhoid germ as a bacteriologist?

A. None whatever.

Q. Have you ever separated the typhoid germ in the laboratory from the excreta of typhoid patients?

A. I have not.

12911 Q. Are you sufficient of a bacteriologist to do so?

A. I am not.

Q. Have you ever made any experiments of your own upon the longevity of the typhoid germ in sewage?

A. I have not.

Q. Have you made any experiments of your own upon the longevity of the typhoid fever germs in sterilized water in lake water, in the water of the drainage canal or the waters of the Illinois River?

A. I have not.

Q. Have you examined and read the experiments introduced in evidence in this case and made by Professors Jordan, Zeit and Russell?

A. I have.

Q. Have you read the entire testimony in regard to those experiments or has it been told to you?

A. I can not say that I have read it all. My time has been too limited to read all that has been introduced on the subject. I have read portions of it and am familiar with parts of it.

12912 Q. Have you read the experiments of Professors Jordan, Zeit and Russell as carefully as you read the experiments of Hiram F. Mills?

A. Yes sir.

Q. In reading the experiment of Hiram F. Mills, have you read the technique of the manner in which the experiment was conducted and the method employed in the detection of the typhoid germ?

A. Yes sir.

Q. How do the methods employed by Hiram F. Mills compare with the methods employed by Jordan, Zeit and Russell in the detection of the typhoid germ?

A. I should not consider myself competent to criticize the technique of either Mr. Hiram F. Mills or Messrs. Jordan, Zeit and Russell.

Q. Have you read the experiments made and introduced in evidence in this case in the testimony of John W. Hill of Philadelphia, who is in charge of the filtration bureau?

12913 A. I have read as much of it as was possible in the time at my disposal.

Q. I mean the testimony on the experiment of the typhoid germ in the water of the Schuylkill River?

A. I do not think I have read that. I do not remember to have seen that.

Q. In the chart which you have introduced in evidence, in which you testified that since the opening of the drainage canal the typhoid rate in the cities on the watershed of the Illinois River has gone up since 1899 to 1900, exclusive of Chicago, I believe you called special attention to that feature of the chart in your direct testimony did you not?

A. It seemed to me a variation in the general result worth noticing.

Q. How do you account for that rise as evidenced on that chart from 1899 to 1900?

12914 A. I have not attempted to account for it particularly. I think I observed that the line was fairly uniform and that the only marked departure from the uniformity was that rise which I considered not of large amount.

Q. For the years 1900, 1901 to 1902 there is a fall in the typhoid along the Illinois River, exclusive of Chicago, is there not, as evidenced by this chart?

A. There is a slight fall.

Q. How do you account for that?

A. I have not attempted to account for it.

Q. Upon the Mississippi River from 1899 to 1901 there is a rise in the typhoid rate as evidenced by the chart. How do you account for that?

A. I have not attempted to account for that, or for any of the minor fluctuations except on the theory that there are always fluctuations in any such death rate, and that in order to be of interest they should be somewhat marked.

Q. There was a rise in St. Louis from 1898 to 1899 to 1900—was that not evidenced by this chart?

A. That was on the face of the returns from the typhoid deaths.

12915 Q. From the face of the returns in each instance is it not?

A. In each instance with the exception noted in the lower right hand corner of the chart which refers to a dotted line leaving the deaths in St. Louis at the year 1898 and rejoining that again in the year 1901. In this case the face of the returns are plotted in the usual line in which all of the St. Louis deaths are situated, and the possible deduction due to localized epidemics is shown by this dotted line above referred to. With that exception the diagram is constructed wholly from the deaths agreed upon in this case.

Q. Is there anything on this chart that shows that the rise of typhoid fever in the city of St. Louis is due to the typhoid condition in the city of Chicago?

A. I think there is.

Q. Will you point out on this chart where such a fact appears?

A. The diagram shows that the deaths on each of the three water sheds contributing to St. Louis are fairly and reasonably uniform, barring the minor fluctuations which always occur in such death rates from various slight causes, but the diagram further shows that at and from the year 1900 a very large number of deaths were added to the normal deaths upon the combined water shed by the opening of the drainage canal. In two years after the opening of the drainage canal the total number of deaths attributable to the water supply of St. Louis had been more than doubled, in marked contrast to the fairly uniform conditions which prevailed on each water shed, excluding the sanitary district of Chicago. 12916

Q. And is that evidenced by the chart which you have referred to?

A. I think it is.

Q. Have you seen the charts prepared by Professor Mason, comparing the typhoid conditions in Chicago with the typhoid fever conditions in St. Louis by the month?

A. I have not. They do not seem to me to be among the records which I have examined in this case.

Mr. Jeffries: I want to state in this connection that the
charts offered in evidence by Professor Mason and about which
this evidence concerns were placed in the hands of the
12917 Commissioner at once and the complainant since that
time has not been in condition to examine them or have
witnesses examine them.

Mr. Todd: Q. Have you compared the typhoid condition in the city of Chicago by the months with the typhoid condition in the city of St. Louis by the months?

A. I have not.

Q. Would such a comparison, allowing thirty days interval between Chicago and St. Louis to intervene, shed any light upon the question as to whether Chicago has any effect upon the typhoid conditions in St. Louis in your opinion?

A. I should be afraid that it would induce too many fluctuations and variables of the greatest value, I should prefer to take the averages for the year, showing in a more marked manner any main distinguishing characteristics.

Q. Might not an increase in the typhoid fever in the city of St. Charles be expressed in the typhoid conditions in the city of St. Louis?

A. Possibly.

Q. Might not an increase of typhoid fever in Kansas City
be expressed in the increase in typhoid fever in the city of
12918 St. Louis, taking into consideration that sixty-seven per
cent. of the water consumed in St. Louis is Missouri River
water?

A. It might possibly but so far as I have been able to observe it does not.

Q. Can you tell whether the infection that afflicted St. Louis comes from St. Paul, Minneapolis and the cities on the Mississippi River, the cities on the Missouri river or the cities on the Illinois River?

A. I think when conditions are marked and data fairly adequate that it is possible to tell.

Q. Do you consider that any of the typhoid fevers cases in the city of St. Louis is due to Missouri River water?

A. There is always that possibility.

Q. What is your opinion as to whether any of the typhoid fever in St. Louis is due to Missouri River water?

A. My opinion would be that a percentage of the normal typhoid deaths in St. Louis prior to 1900 would very probably be due to the contamination from waters of the Missouri River.

Q. What cities on the Missouri River would you attribute the infection to?

12919 A. I should want to make a more detailed study of the case before venturing an opinion. My endeavor has been to study the problem by water sheds rather than cities, except in the case where I have added the sanitary district of Chicago.

Q. Would you regard the conditions at St. Charles as contributing as much typhoid as the city of Kansas City, to the city of St. Louis?

A. It is probable that it may have an equal effect upon the normal typhoid deaths in St. Louis.

Q. How far would you consider the city of St. Charles by water in point of time from the St. Louis intake?

A. I am not exactly informed as to that.

Q. The distance has been estimated by the river at approximately forty miles. Are you acquainted with the hydraulic conditions of the Missouri River?

A. To some extent.

Q. If one typhoid fever patient could create the epidemic at Plymouth, Massachusetts, what effect in your opinion would the number of cases of typhoid deaths in the city of St. Charles as evidenced by the statistics which you have studied, have upon the water supply of St. Louis?

A. There are always possibilities of contamination from 12920 unexpected sources.

Q. Would you say that beyond all reasonable doubt the typhoid fever as you know it te exist in the city of St. Charles is not responsible for the great proportion of the typhoid fever in the city of St. Louis, bearing in mind what you know about the epidemic at Plymouth, Pennsylvania, and of other epidemics that you have studied and introduced in this case?

A. I should be inclined to think from my diagram that the typhoid deaths in St. Charles might have influenced the normal typhoid deaths in St. Louis prior to 1900 to some unknown percentage.

Q. Since 1900?

A. I should be disinclined to think that since 1900 the typhoid in St. Charles could have been responsible for so marked a change in the number of deaths in St. Louis from typhoid.

Q. Does the number of people afflicted with typhoid fever in a given city depend upon the number of people that have typhoid fever above on the water shed?

A. It does to some extent when you are considering averages over long periods.

12921 Q. How do you account for the Plymouth epidemic that was due to one typhoid fever case?

A. There are always exceptional occurrences of that kind.

Q. Might not such an exceptional occurrence happen between St. Charles and the city of St. Louis?

A. It is within the range of possibility.

Q. Being in the range of possibility, can you assert that the greater proportion of typhoid fever in the city of St. Louis can not be attributed to such a possibility beyond all reasonable doubts and to a moral certainity?

A. In the absence of direct proof that the typhoid deaths in St. Charles have been responsible for the rise in deaths in St. Louis, we are obliged to proceed on the theory of probability, and the theory of probability would indicate that the preponderating number of deaths, wherever they may be found, are the responsible cause, therefore I would be disinclined to attribute (in the absence of direct proof) the rise in the typhoid deaths in St. Louis to the typhoid deaths in St. Charles.

Q. Do you employ the theory of probabilities in drawing your conclusions that the typhoid increase in St. Louis
12922 is due to Chicago?

A. Whenever we deal with a problem of the magnitude of this problem and its complications, we are obliged as one of the contributing data to proceed on such theory.

Q. And that theory has been employed by you in giving your opinions on the effect of the opening of the canal upon the typhoid condition in St. Louis?

A. As one the data from which I draw my conclusions.

Q. What importance do you attach to the typhoid conditions on the water shed of the Missouri River?

A. The importance that is shown by the plotting of their deaths upon this diagram in its relation to the deaths from other sources.

Q. Anybody could plot those deaths on a diagram could they not?

A. Well, they might not always be able to accomplish that in such a way that they would bring clearly out the facts.

Q. But my question is, what importance do you attach regardless of the diagram to the number of cases of typhoid fever on the water shed of the Missouri River as affecting the
12923 sanitary quality of that river?

A. I should attach this importance, that I observe that the typhoid deaths on the Missouri water shed, all things considered, have been fairly uniform for the whole period shown, and therefore whatever percentage of contributory infection the Missouri water shed may have produced prior to 1900, I should be inclined to attribute in equal degree to the period since 1900.

Q. Do you regard the water of the Missouri River in its raw state as a safe drinking water for drinking and domestic purposes?

A. I do not.

Q. As treated by the settling basins of St. Louis, do you regard it as a safe drinking water for drinking and domestic purposes?

A. I should say that it has in all probability been greatly improved in its general character.

Q. Is it not a fact that the water of the Missouri River has been deteriorating as a safe drinking water for the last twenty-five years, and each year more so?

A. I think that may be safely assumed and the same is probably true perhaps of all our western rivers.

12924 Q. Do you regard the Mississippi River above Grafton as a safe drinking water?

A. I do not.

Q. Do you regard the water of the Illinois, Mississippi and Missouri Rivers, assuming that the sanitary district of Chicago was eliminated, and treated as it is treated in the settling basins at St. Louis, as a safe drinking water to be used by a city of 800,000 inhabitants, such as St. Louis is, as it is at present used?

A. I do not regard it entirely so.

Q. If you were selected as a sanitary egineer or a hydraulic engineer to pass upon the quality of the water of the Mississippi River, a mixture of Missouri, Mississippi and Illinois River water, excluding the sanitary district of Chicago, treated as it is now treated, would you recommend it as a safe drinking water, free from typhoid infection?

A. I should not like to so recommend it.

Q. What were the discharges of the Illinois River at the time that Randolph made his float experiments?

A. I was not able to discover. I believe Mr. Randolph 12925 gave some gaugings at Peru and gauge readings at La Salle, but as I have no data for this cross sections, I am unable to determine what the stage was in terms of the discharge.

Q. Was it at high, low, average, mean or below mean flow of the Illinois River?

A. If I were obliged to determine from such evidence as I am able to derive from his testimony, knowing that the time when the floats were run, was in the month of July, and knowing that the total time of transit in comparison with Professor Van Ornum was as 10 is to 15, I should be inclined to judge that the stage at which Mr. Randolph's experiments were taken were the average low waters of mid summer.

Q. If you do not know the stages of the river and its flow, how are you able to give that opinion?

A. I do not think that that opinion is as valuable as it would be if I did know the exact stages of the flow.

Q. It is more in the nature of a guess than an opinion based upon scientific knowledge?

A. It is an intelligent guess.

Q. Did you ever measure the current from the Bear Trap
12926 dam to Lake Joliet with floats yourself?

A. I believe not personally.

Q. Do you know what the fall is from the Bear Trap dam to Lake Joliet?

A. Yes sir.

Q. Knowing the fall and the volume of water, can you figure the velocity of flow?

A. Yes sir.

Q. Can that be accurately ascertained by that method?

A. Not as accurately as it could by the floats.

Q. Did you have it done?

A. No sir.

Q. With floats?

A. No sir.

Q. When you corrected Professor Van Ornum's time, what method did you employ in doing it?

A. I calculated the mean velocity by the cross-section and fall and deducted the surface velocity by dividing by .8.

Q. Is there a better method than floats such as Professor Van Ornum used?

A. There would not be if the same stages were considered,
12927 but it is impossible to predicate the surface velocity at
another stage from the float experiments of Professor Van Ornum, with any very great exactness. I might say however that I used the speeds found by Professor Van Ornum for the lower stage as a check upon the calculations which I made for the slightly higher stage which I got.

Q. In figuring out the average time between Chicago and St. Louis, what conclusions did you come to?

A. That at most stages of the river uninfluenced by flood of any kind, the time of passage of the pollution vehicle would be in the neighborhood of the float experiments, as determined by Mr. Randolph or thereabouts, but not reduced to mean velocity, and that in times of slight or medium rises, the time of passage of the pollution vehicle would be aparently in accordance with the experiment of Professor Van Ornum, and that in time of very great floods, such as occurred in 1902, and I believe in 1888, and at one or two other times in my recollection, the time of passage might be reduced to eight days or less.

Q. In the times of flood there would be greater dilution would there not?

12928 A. Yes sir.

Q. And dilution minimizes danger from infection, does it not?

A. Not altogether; it increases the longevity of the typhoid germ.

Q. But is disseminates them in a greater body of water thereby diminishing on the theory of probability, the danger from infection does it not?

A. I should think that would be a fair statement, yes sir.

Q. In figuring on Mr. Hering's chart that is introduced in evidence, did that chart show a population of 13,000 people above the intake tower?

A. I have not seen the original chart that Mr. Hering produced but a zinc etching which has been reduced in size, so that it is difficult to determine what the actual figures might be from the scale. I have, however, relied upon the statement of Mr. Crane, who prepared the chart, with reference to those figures.

Q. By the method that you employed on the Illinois end of this chart, applying that same method to the Missouri and Mississippi Rivers, will you state what the results show?

12929 A. I have not undertaken to reduce the Missouri and Mississippi Rivers to terms of typhoid pollution at St. Louis in the manner shown by Mr. Hering.

Q. Why?

A. Because I did not deem them pertinent to this inquiry.

Q. The chart which Mr. Hering introduced in evidence showed a comparison between the conditions that obtained on the Illinois, Mississippi and Missouri Rivers, based upon Mill's experiment, did it not?

Mr. Jeffries: Object to the question for the reason that this inquiry is not to determine the extent of the pollution and the infection of the Mississippi River above Grafton and the Missouri River, but that the inquiry is directed solely to the effect that the sewage discharged from the city of Chicago has upon the waters of the Illinois River and consequently upon the waters of the Mississippi River below Grafton.

A. Yes sir.

Mr. Todd: Q. If you had carried out the comparison contemplated in the chart introduced by Mr. Hering, would the pollution from the Illinois River be as great as the pollution
12930 from the Mississippi and the Missouri Rivers, figured in
the same manner that you have figured the chart which you introduced?

A. I am not able to say, not having worked out the data.

Q. In order to make a comparison between your method of calculation and the method employed by Mr. Hering, do you not think it would have been more accurate to have carried out your charts for the three rivers instead of one?

Mr. Jeffries: I object to the question for the reason that it is not competent evidence in this case to make comparison between the relative pollutions of the three rivers, the question involved in this case being as to the effect of the sewage discharges from the city of Chicago upon the Illinois River and Mississippi River below Grafton, and for the further reason that the chart introduced in evidence by this witness based upon the chart of Mr. Hering, which was prepared by Mr. Crane, was not introduced for the purpose of showing a comparison between the pollutions of the three rivers, but for the purpose of showing the effects of the sewage of Chicago upon the waters of the Mississippi River below Grafton.

Mr. Todd: In reply will state that the chart speaks for itself and shows the opposite of what the counsel con-
12931 tends.

Q. Question read.

A. I do not see how it could.

Mr. Todd: Q. In the chart which you introduced, computed upon the method which you adopted, I believe you stated that at a maximum flow in the Illinois River, the pollution at the intake tower of the chain of rocks was equal to an infection from a population of 960,000 people. Is that correct?

A. I think I stated that the method of Mr. Hering, worked out with the corrections which I have suggested, would indicate that.

Q. Did you not understand Mr. Hering's chart to be for the purpose of showing the relative pollutions of the three rivers with a ratio of 13 to 97 and 106, whether expressed in people or otherwise?

A. I understood that that was one of the facts which he endeavored to bring out, but I also understood from the study of his chart that he was endeavoring to bring out as well the probable amount of pollution which would reach the intake at the chain of rocks from the sanitary district of Chicago, based upon the experiments of Hiram F. Mills and the float experiments of Mr. Isham Randolph.

12932 Q. You did not understand his testimony and the chart to mean that there was a city of 13,000 people dumping sewage into the Mississippi River at the intake?

A. I took it that that was the practical effect of his reasoning.

Q. And under your interpretation of the chart, supplemented by your method of calculation, there would be, at maximum time, a population of 96,000 people?

A. There would be.

Q. In the testimony that you have given when filter plants have been in operation, and the cities using such filter plants have been the victims of a typhoid fever epidemic through the mismanagement or other cause of the plants, are any of those plants to which you refer owned and operated by the municipality itself or by private water companies?

A. They are about equally divided between the two.

Q. How many of these epidemics were due to shutting down of the filters and turning in the raw water to the water supply of the people?

A. I think two.

Q. Which ones?

12933 A. Butler, Pa., and Beaver Falls, Pa.

Q. That was not the cause then of the filter plant as much as the carelessness of the water company?

A. Well, it was the fault of the filter plant to adequately protect the water supply through the carelessness of the employe connected with it.

Q. In the matter of the Butler Company do you know whether it was a question of the employes or the question of the management that took that filter plant out of operation and turned the raw water in?

A. I think it was, in that case, the question of the management.

Q. Are you familiar with the causes that led to the epidemic at Butler?

A. Somewhat.

Q. In the case at Beaver Falls the same thing is true is it not?

A. I should say that it was.

Q. What is the cause of greatest expense in constucting a filter, matters in suspension or infection?

A. That will depend very much upon the kind of water and its amount of pollution that is to be dealth with.
12934 In a turbid water free from typhoid pollution, the turbidity will undobutedly be the cause of the greatest expense, but in a water comparatively clear, or clear most of the time, but subjected to typhoid infection, the infection will undoubtedly be the greatest cause of expense.

Q. Which would it cost the most to filter, the Missouri, Mississippi or the Illinois River water?

A. Based on turbidity the Missouri River water. Based on typhoid infection the Illinois River below the sanitary district of Chicago.

Q. I mean at Grafton?

A. I should say at Grafton the typhoid infection would be at least equal in cost to the turbidity.

Q. The Mississippi?

A. For the Mississippi River I should think the cost would be about equal for both turbidity and typhoid infection.

Q. Would the cost of the Mississippi be greater or less than that of the Illinois?

A. It would be greater for turbidity and less for typhoid infection.

Q. In the general cost of filtering the two rivers taking
12935 everything into consideration for an equal sized plant,
would it cost any more to filter the Illinois River at Grafton than it would the Mississippi at Grafton?

Mr. Jeffries: I object to the question for the reason that the question assumes that the turbidity of the two rivers is the same and that while increased turbidity might to some extent increase the cost of the construction as well as the operation, but inasmuch as the cost of the construction and operation of a given plant for a given river is determined upon the question of turbidity and the well known and probable existence of infectous material, that by reason of the introduction of the additional infectous material from the Illinois River, the cost might or might not be greater, and therein lies the impropriety of the question, and for that reason the question is misleading and does not contain sufficient facts upon which to base an intelligent and reasonable answer.

Q. Question read.

A. I should say that it would for the reason that in filtering the Illinois River at Grafton we are obliged at first to provide for the cost of removing the turbidity which, while
12936 it is less than the turbidity of the Mississippi is nevertheless very great at certain seasons of the year, and in addition to this question of alluding to provide for the cost of protection against typhoid pollution which in my opinion would be greater than in the case of the Mississippi River.

Mr. Todd: Q. You would recommend filtration for the water supply of the city of St. Louis would you not?

A. In any event.

Q. If the sanitary district of Chicago should be eliminated, you would still recommend a filtration system for the water of the city of St. Louis would you not?

A. I would.

Q. When in the employment of men to supervise and attend a filter plant of that kind you would get the highest skill, would you not?

A. Yes sir, reasonably so.

Q. If the sanitary district of Chicago should turn its sewage in, you would still recommend the filtration system would you not?

12937 A. Yes sir, but I should recommend at least a double filtration system, preceded by successive stages of sedimentation or some additional form of protection to that which

I would suggest for waters from the water shed, excluding the sanitary district of Chicago.

Q. Would you employ any less competent men to operate the filter plant with the sewage of Chicago eliminated, than you would with it present?

A. I am inclined to think I should want a very high grade of intelligence at the head of such a plant, if it were going to provide against typhoid contamination as against perhaps less expensive treating if it were going to deal with turbid waters or waters of very rare pollution.

Q. Where would you get the men from to operate such a plant that had experience in a filter system the size that would be needed in the city of St. Louis?

A. Albany, Berlin, London, or men in this country who had given those large filters close study and attention.

Q. Would you put men in charge of a filter plant with less capability and experience if the sewage of Chicago was
12938 eliminated than you would if it were present?

A. Not to any very marked degree. I should think I would be a little more cautious and would recommend a little greater expense, but I do not think that the difference in the cost of filtration would be very much affected by that particular item.

Q. In the construction of the filtration plant at Philadelphia —which is the largest in the United States is it not?

A. Yes sir.

Q. Do you know whether there is any element of cost entered into in that plant in order to guard against infection?

A. Yes, I think the preliminary filters can be properly so considered.

Q. If John W. Hill who was constructing that plant should testify that infection was no element of cost in the operation and installation of that plant, would his opinion have any weight with you?

A. I think I should be disinclined to agree with him.

Q. Have you constructed any filter plant wherein you have made additional cost to guard against infection?

12939 A. I do not think I have personally, with this exception that I have provided for the filtration of sewage as well as the purification of water in a plant deriving its water supply from the same source into which it emptied the sewage.

Q. Have you designed any filter plant where the question of infection was eliminated, in the purification of water?

A. I think I have not designed any plant where it was wholly eliminated. In some of the places it was a very minor consideration?

Q. Has that consideration of infection added to the cost of any plant which you have been connected with?

A. Yes at the plant where I considered sewage purification.

Q. What was the size of the plant to which you refer and where located?

A. The plant was situated at Lake Forest, Illinois, a suburb north of Chicago, which derives its water supply by pumping from Lake Michigan and empties its sewage into Lake Michigan. They filter the water, and filter the sewage.

Q. What was the cost of that plant and its capacity?

A. The plant for the filtration of the water cost from
$7,000.00 to $8,000.00. The plant for the purification of
12940 the sewage cost $7,500.00, and might be taken as the
measure of the added cost due to known pollution.

Q. What is the population of Lake Forrest?

A. About 2,000 people.

Q. Are you acquainted with the recommendations made in the report of Mr. Hazen upon the filtration of the water at St. Louis when he served as a special commissioner?

A. I have read his report.

Q. Have you designed a filter plant for any city in the country larger than Lake Forest?

A. Yes sir, I have designed a plant last summer for Ottumwa, Iowa.

Q. Was it installed?

A. Not as yet.

Q. Have the designs which you have made for Ottumwa been accepted by the city of Ottumwa?

A. They were not made for the city of Ottumwa. They were made for a private company applying for the franchises at Ottumwa.

12941 Q. Have the plans which you have made for Ottumwa been accepted?

A. Not as yet.

Q. Do you know whether they will be accepted or not?

A. Well, the chances are against it.

Q. Then the only personal practical experience that you have had in connection with the building of filtration plants is limited to Lake Forest?

A. No sir, I have been engaged upon a plant at Terre Haute, Indiana, quite a large plant.

Q. A filtration plant?

A. Yes sir. I was in co-partnership with the responsible engineer in charge and superintended it.

Q. When was this plant at Terre Haute built?

A. In 1889.

Q. What was its cost?

A. My recollection is that it cost between forty and fifty thousand dollars at that time. It was added to later on.

Q. Did you design that filtration plant?

A. No sir, I had the experience of being connected with
12942 its construction. It was a mechanical filter plant, however, and mechanical filter plants are really largely designed by the mechanical filter companies.

Q. It was a patent filter?

A. A patent filter, yes sir.

Q. Then in your experience in the installation of this patent filter and building the filter at Lake Forest, does that include all your personal connection with the construction of filters?

A. My personal connection with the design and construction of filter plants has been rather more limited than my experience in the design and construction of sewage plants. At the same time I have designed a number of important plants for the purification of water supplies and constructed others, and had to do with the operation of still others, perhaps to the total number of eight or ten all together.

Q. But in the active construction and building of filter
12943 plants, where you have figured on cost, and were responsible for the filters, are these the only two plants that you have been connected with in that way?

A. I believe they are.

RE-DIRECT EXAMINATION.

Mr. Jeffries: Q. You mean by your last answer that that is all you have had supervision of the construction of the plant?

A. Yes sir.

Q. As far as the experience in the construction is concerned?

A. Yes sir.

Q. State whether or not you have been called in consultation in reference to the repairing of filtration plants and the cost of the repairs and the cost of maintenance and such suggested improvements as might take place from time to time?

A. I have been so engaged in quite a number of places. I would not be able to say them all off hand, I should say at least a dozen places where I have advised as to the construction of filters or modifications of them or the designing of them. I am now working on some very large designs and recom- 12944 mendations for filter plants, and I am familiar through personal inspection and the collection of data with a very large number of such plants which I have visited abroad.

Outside of the patent mechanical filters, there have not been as yet a very great many filters built in the United States from special designs.

Q. Mr. Alvord, Mr. Hering, in his testimony, was asked this question: "In the construction of a filtration plant, is it not a fact that sanitary engineers take into consideration the extent of the infecting material discharged into a stream above in determining the character of the plant to be recommended," and in answer thereto said, "We do take that fact into consideration." The further question was asked, "In considering the construction of a filtration plant for the filtering of a water supply for a city which is taken from a running stream, sanitary scientists would recommend the use of a larger quantity of sand, if it be that character of a plant, per 100,000 population than if such water be subjected to the sewerage of a city of 1,000 population would they not," and in answer thereto, Mr. 12945 Hering said: "The population would cut no figure in my mind. We would under peculiar conditions possibly recommend one system of filtration for a highly polluted water, while we would be satisfied with another system of filtration in a very slightly polluted water." I will ask you if in the construction and operation of a filtration plant, sanitary engineers do not take into consideration the fact that when water is highly polluted with infected material that more complex construction must be obtained and that complex construction or plant more perfectly marked and that by reason of such superior construction and cautious maintenance a municipality would be required to employ more efficient men and be more cautious and observant as to the operation of the plant, and that this fact is well recognized by sanitary engineers and by the officers of the municipalities where filtration plants are being constructed.

Mr. Todd: Object to the question as not re-direct examination, and as leading. It is not rebuttal and therefore incompetent, irrelevant and immaterial.

A. I think this is a fact well recognized.

12946 Mr. Jeffries: Q. Is it not a fact that as the infection material is increased in a running stream that is being filtered that it is recognized by all sanitary engineers that the construction must be more perfect, of a higher grade, and that the equipment, the maintenance and the character of the employes more efficient?

Mr. Todd: Object to the question as to the previous question.

A. I think that it is.

Mr. Todd: Move to strike out the answer for the reasons heretofore given.

Mr. Jeffries: Q. In the filtration of a given water when the filtration plant has been constructed, assume that subsequent to the construction of this filtration plant the sewage disposal of a large and populous city be so disposed as to find its way, or the deleterious substances that are found therein, into the waters of that river above the filtration plant, state whether or not in your opinion more precaution and greater care should afterwards be maintained in the operation of that

12947 plant?

Mr. Todd: Object to the question for the same reason as heretofore stated.

A. In my opinion they should.

Mr. Todd: Q. If you were going to construct a filtration plant for the city of St. Louis would you construct it less stable and durable and with infected material to filter in order to filter the water of the Mississippi River with the sewage of the drainage canal eliminated than you would if that sewage was in it?

A. I do not think that the stability or permanency would enter into the question. I think it would be simply a question of the number of stages into which the purification would be divided, and the resulting complexity of the plant as a whole.

Q. But in answer to one of Mr. Jeffries' questions you stated that it would not require the same high skill in the putting up of the plant under the one condition as the other. As a matter of fact building a filter plant to filter the amount of water necessary for the city of St. Louis, you would employ the very best material and the highest skill obtainable in
12948 such a plant under either condition would you not?

A. So far as the actual construction was concerned, yes. But in so far as the complex arrangement of the plant is concerned, no.

Q. In the employment of the men to handle the filter that would be a matter that would be left to the municipality would it not?

A. I presume it would.

JOHN W. ALVORD.

ADJOURNED until 2:30 P. M., May 26, 1904.

12949 Room 282, Southern Hotel, St. Louis, Mo. 2:30 p. m., Thursday, May 26, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

E. E. LOCHRIDGE,

a witness called on behalf of the complainant, being duly sworn by the Commissioner, was examined in chief by Mr. Jeffries, and testified as follows:

Q. State your name?

A. E. E. Lochridge.

Q. What is your address?

A. Boston, Massachusetts.

Q. Where were you educated?

A. After graduating from the high school at Elkhorn, Wisconsin, I entered Beloit College in which I pursued courses in sciences, giving particular attention to the study of chemistry, and from this college I graduated with the degree of Bachelor of Science, in 1898. During my senior year I acted as private assistant to Professor E. G. Smith, and under his
12950 direction studied questions of water supply with special reference to the water supply of cities and towns.

Immediately after graduating from Beloit College I served as instructor in Chemistry for two terms at Drury College, Springfield, Missouri. I then returned to Beloit, having been appointed a regular instructor in Chemistry in Beloit College, but again served a large part of my time as private assistant to Professor E. G. Smith in further work on water supplies, mainly from the chemical point of view.

In 1900 I took the regular and some special courses in bacteriology at the University of Chicago, in the department of E. O. Jordan. I then resumed my duties as private assistant to Professor Smith. In the course of my work with him I have had occasion to visit many public and private water supplies and to examine such supplies and to study and investigate several epidemics of typhoid fever among which I may mention the epidemic at Rock Island, Illinois, Baraboo, Wisconsin, and Ashland, Wisconsin.

I also studied the operation of filters for municipalities
12951 in a practical way at Davenpart, Iowa, Cedar Rapids, Iowa, Rock Island, Illinois, Ashland, Wisconsin, Warren, Ohio, Kankakee, Illinois, Binghampton, New York, and two filter plants connected with the water supply of the Borough of Brooklyn, New York.

During the years 1902 and 1903 I attended the Massachusetts Institute of Technology, in Boston, as a graduate student, taking the regular courses in sanitary engineering.

Q. State whether or not at this school you also pursued advanced courses in bacteriology?

A. Yes, sir.

Q. And sanitary science?

A. Yes, sir, and sanitary science.

In June, 1903, on the recommendation of Messrs. Samuel M. Gray and George W. Fuller, consulting engineers for the special commission on water supply of the city of Springfield, Massachusetts, I was appointed by that commission to make special studies on the question of purification of the water supply of that city. This work involved experimental in-
12952 vestigation of the various methods of double filtration of water and as resident engineer in charge of this work I had in my employ a number of trained assistants. A report of this investigation has recently been published.

During my residence in Springfield an epidemic of typhoid fever broke out in one section of the city, which epidemic I investigated partly on my own account and partly in co-operation with the secretary of the local board of health.

Q. Mr. Lochridge, I will ask you to state whether or not you have examined the tables of typhoid fever statistics for St. Louis, introduced by witnesses and now formally a part of the record of the defendants in this case, and especially introduced by Dr. Barker on October 24, 1903?

A. I have.

Q. I will get you to state whether or not the number of typhoid fever deaths given upon that table for the years 1896 to 1902, inclusive, is approximately correct?

A. It differs only slightly from the results obtained by compiling the deaths attributable to typhoid fever in the record books of the mortuary office.

Q. I will get you to state whether nor not you have made a special study of the tables from typhoid fever and
12953 other fevers in the mortuary office of the board of health of the city of St. Louis?

A. I have.

Q. Will you state whether or not in your opinion any comparison of the typhoid fever deaths previous to 1896 with those subsequent to 1896 would yield or would be practicable as a means of determining whether or not typhoid fever had or had not increased in St. Louis after the opening of the Chicago drainage canal on January 17, 1900?

MR. TODD: Object to the question for the reason it is not rebuttal as the entire typhoid fever conditions in St. Louis for ten years prior to the opening of the drainage canal were introduced in evidence by Dr. Ravold and supplemented by charts of various kinds as to the typhoid conditions of St. Louis, and is therefore incompetent, irrelevant and immaterial.

A. I do not believe that any such comparison is either practicable or feasible for the reason that while previous to 1896 the intake of the water works of the city of St. Louis was so located as to expose the water supply to infection from sewers coming from the city, and during 1894 and 1895 the 12954 intake was removed to a point further up the Mississippi river at the chain of rocks, above any such contamination.

In order to show that the great change in the typhoid fever mortality of the city of St. Louis, at the time the intake was moved, I have prepared a diagram which serves to illustrate this point, as well as certain other points to which I have occasion to refer hereafter.

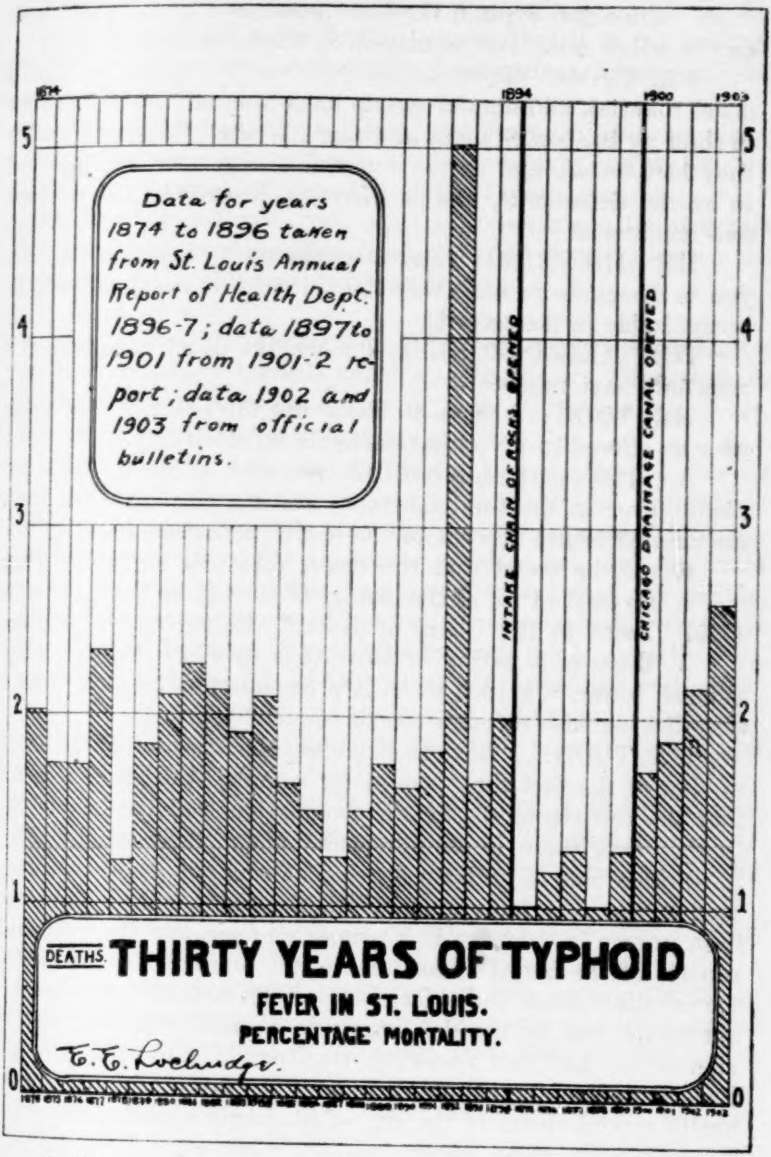
MR. TODD: I move to strike out the answer for the reason it is not rebuttal as the whole matter was gone into by complainant in chief by nearly every witness who testified in this case on the part of the complainant, and it is therefore incompetent, irrelevant and immaterial, and is not rebuttal evidence.

MR. JEFFRIES: Q. Will you produce in evidence this diagram to which you have referred in your last answer?

MR. TODD: Objected to for the reasons heretofore stated.

A. I will. It is as follows:

12955 **Complainant's Rebuttal Chart No. 3.**



E. E. Lochridge.

12956 MR. JEFFRIES: Q. Will you read in evidence this table and explain the facts presented by it in the manner in which such representation is made by the chart.

MR. TODD: Object to the question for the reason that it is not rebuttal, and similar charts have been offered in evidence in chief by the complainant as going into the original case after they had rested, and as not rebuttal of any new evidence put in by the defendants, and is therefore incompetent, irrelevant and immaterial.

MR. JEFFRIES: Mr. Commissioner, I would like for you to designate in some way the title of this chart so as to be recognizable in the record.

THE COMMISSIONER: I mark the chart complainant's rebuttal chart number 3.

MR. TODD: I move to strike out the chart for the same reasons offered in my objection to its admissibility.

A.- This chart represents the per cent. of deaths from typhoid fever to the total mortality for the city as taken from the printed health records of the health department.

It will be noted that the death rate was uniformly high up to the time of the change of the intake from Bissell's

12957 Point to the Chain of Rocks. Following this change there is a period of five years in which the mortality is much lower. In 1900 there is a considerable increase and a step like increase through the subsequent years.

MR. TODD: I move to strike out the answer and the chart in view of the fact that counsel for complainant has contended that the reports of the health commissioner of the city of St. Louis,—that there is no agreement about their admissibility in evidence and if such an agreement was not made, as I contend it was, the facts upon which the chart is built have not been proven in evidence in a proper manner, and the published reports of the board of health are not competent evidence for the complainant, if the objection made by counsel for complainant to the use by the defendants is a valid objection, and in view of the fact that these reports from 1874 to 1903 have not been proven as the official report of the health department or health commissioner of the city of St. Louis, and that the chart is based upon those public reports, I move to strike out the answer and the charts as it is not competent evidence and is not based upon any facts that have been proven in this 12958 case, and for the further reason that it is not rebuttal evidence and is therefore incompetent, irrelevant and immaterial.

MR. JEFFRIES: Q. Have you examined the records of the deaths from other fevers in the mortuary office of the health department of the city of St. Louis; remittent, intermittent, typho malaria, congestive and simple continued fevers for the four years preceding and the four years following the opening of the Chicago drainage canal?

A. I have.

Q. Please state what you found upon your examination of these mortuary records respecting the deaths from typhoid fever, remittent fever, intermittent fever, typho-malaria fever, congestive fever, and simple continued fever?

MR. TODD: Objected to for the reason that the records are the best evidence, and in view of the fact that counsel for the complainant contends that there is no agreement existing between the counsel for the State of Missouri, and the State of Illinois and the Sanitary District that the official 12959 published reports of the health commission of St. Louis shall be used in evidence by both sides, then it is incompetent to have the witness testify to what the records in the mortuary department of the city of St. Louis may show in regard to other things, and it is therefore incompetent, irrelevant and immaterial.

MR. JEFFRIES: As to this objection I refer to and stand upon the statement made by me on the first day of the resumption of testimony at this place and at this time, to-wit, on the 23rd day of May, 1904.

MR. TODD: In reply to counsel will state that I stand upon my objection.

A. I have examined these records and have made tables showing the number of deaths from the causes mentioned in the question in each month of the years from 1896 to 1903, inclusive, which tables are as follows:

MR. JEFFRIES: Mr. Commissioner, I would like for you in some way to identify the tables which have just been offered in evidence.

THE COMMISSIONER: They are designated as complainant's rebuttal charts numbers 4 to 9, both inclusive. 12960

Which said charts are as follows:

E. E. Lochridge

12967 A. In the tables headed "Typhoid Fever Deaths, St. Louis," it will be noted that a double line is placed between the years 1899 and 1900, and in the case of almost every month it will be seen that there is a distinct rise from that point, in the number of deaths for that month in the four following years.

In the tables headed "Remittent Fever Deaths, St. Louis," the total number of remittent fever deaths will be seen to be in the year 1896, 40; in the year 1897, 29; and in the following years 26, 15, 15, 23, 17, 17, respectively, showing in a general way from the year 1898 no change in the mortality from this cause.

In the tables headed "Intermittent Fever Deaths, St. Louis," it will be noted that the deaths from this cause are about the same in number each year, that is 12, 12, 16, 25, 10, 12, 9 and 11, and that with the exception of the year 1899, in which the number was about double that of any of the other years, there has been no change in the number.

In the table headed "Typho-malarial Fever Deaths, St. Louis," the number of deaths from this cause in the year 1896 was 50, in 1897 it was 42, and from that time to 1903 about 30 each year, no marked variation being noted.

In the table headed "Congestive Fever Deaths, St. Louis," it will be noted that there are in 1896 and 1897, re-
12968 spectively, 26 and 22 deaths from this cause, and from 1898 to 1903, respectively, there are 13, 15, 15, 4, 15 and 7 only, and that with the exceptions of the years 1901 and 1903, when the number was perceptibly lower, the number remained precisely the same.

In the chart headed "Continued Fever Deaths, St. Louis," it will be noted that there were but two deaths from continued fever in the four years prior to the opening of the canal and four in the four years subsequent.

MR. TODD: I move to strike out the answer for the reasons given in my objection to the question, and for the additional reasons that the typhoid fever deaths per month was gone into in chief by complainants in Dr. Ravold's testimony and in detail by the months as well as by charts, and is therefore not rebuttal, consequently incompetent, irrelevant and immaterial.

MR. JEFFRIES: Q. State whether or not, in your examination of the mortuary records in the office of the board of health of the city of St. Louis you discovered, during your examination, any tables designated as deaths due to simple continued fever during those years?

12969 MR. TODD: Object to the question for the same reasons heretofore advanced, and the additional reason it is incompetent, irrelevant and immaterial.

A. I find six deaths marked continued or continuing fever, but none marked simple continued fever in the years 1896 to 1903, inclusive.

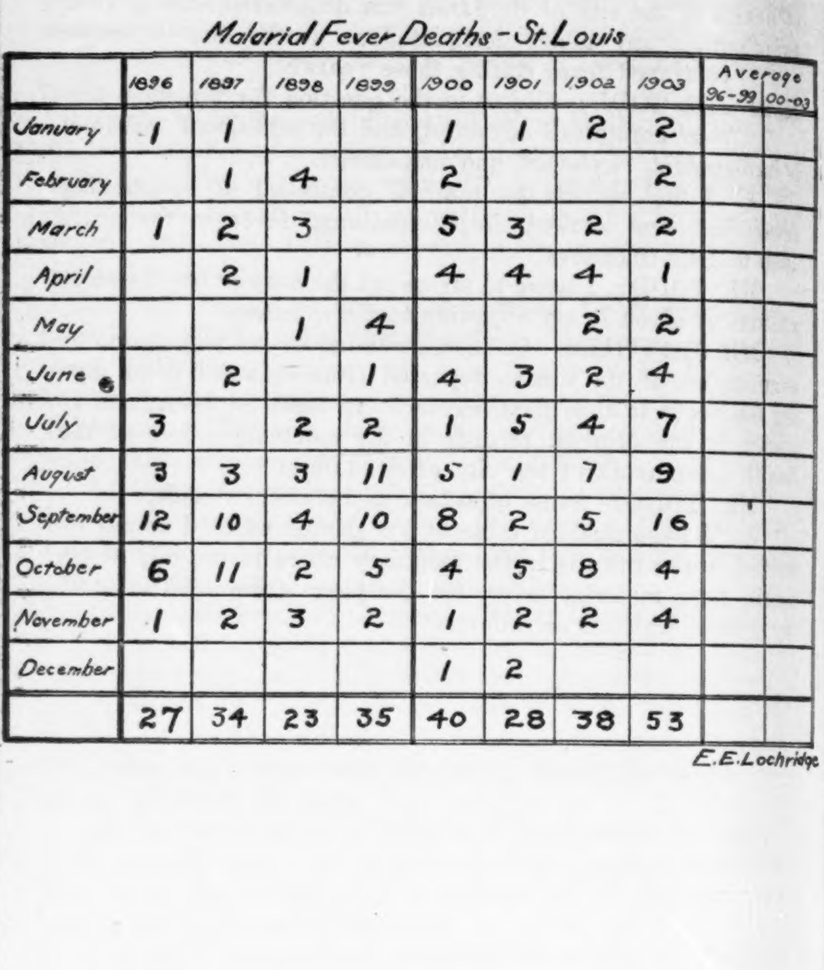
MR. TODD: I move to strike out the answer for the same reasons as given in my objection to the question.

MR. JEFFRIES: Q. State whether or not you made any examination of the deaths reported from malarial fever during the years 1896 to 1903, inclusive, as malarial fever, and as shown in the original records in the mortuary office of the health department of the city of St. Louis?

MR. TODD: Same objection as heretofore made.

A. I have made a table of the deaths which I found recorded in the records in the mortuary office in the city of St. Louis, from malarial fever, for the years from 1896 to 1903, by months, which is as follows:

12970 Chart No. 10.



Malarial Fever Deaths - St. Louis

	1896	1897	1898	1899	1900	1901	1902	1903	Average 96-99	Average 00-03

December					1	2				
	27	34	23	35	40	28	38	53		

E.E.Lochridge

12971 A. The number of deaths from malaria and malarial fever were in the years from 1896 to 1903, 27, 34, 23 and 35, respectively, before the opening of the canal, and 40, 28, 38 and 53, respectively, for the four years since the opening of the canal.

MR. TODD: I move to strike out the answer for the reason heretofore stated in my objection.

MR. JEFFRIES: Q. State whether or not you have read the testimony introduced in evidence by Dr. Barker and Dr. Jordan in this case?

A. I have.

Q. Did you examine the tables of typhoid statistics for St. Louis prepared and introduced by him, and which now forms a part of the evidence of defendant in this case?

A. I have.

Q. I will ask you to state whether or not any of the deaths from the fevers known as intermittent, remittent, congestive and typho malaria and continued fevers for the years 1896 to 1903, inclusive, or all of them taken together, correspond in number with the numbers given by Professor Barker and Professor Jordan, the tables of typhoid statistics
12972 from St. Louis introduced by them in evidence?

MR. TODD: Object to the question for the same reasons heretofore given.

A. Adding together the deaths which I found in the study of the records at the mortuary office from remittent, intermittent, typho-malaria, congestive and continued fevers, I find that for the years 1896 to 1899, inclusive, there were respectively 129, 106, 85 and 86 deaths, and that if the number of deaths which I found in the records in the mortuary office from malaria are added to these, there are in these years respectively 156, 140, 108 and 121 deaths, while Professor Jordan gave for the corresponding years 177, 172, 134 and 148, or the number of deaths which I find recorded on the books in the mortuary office from these causes is a little lower in each year than the list taken by Professor Jordan from the printed health report.

In the four years from 1900 to 1903, inclusive, adding together the deaths which I found in the books in the mortuary office in the city of St. Louis from intermittent, remittent,

typho malaria, congestive and continued fevers, I find
12973 for these years 77, 62, 76 and 73 deaths. Adding to these the deaths which I find of malarial fever for these years, there were 137, 90, 114 and 126 deaths, or a little higher in each year than those given by Professor Jordan.

MR. TODD: I move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. State whether or not there is considerable difference between the data compiled by Professor Jordan and adopted by Dr. Barker and that ascertained by you from your examination of the mortuary records in the health department of St. Louis, and state wherein the difference lies?

MR. TODD: Object to the question for the reasons heretofore stated.

A. Considering the fact that the malarial fevers were in all probability recorded in this list as they do not occur under any other caption, so far as could be discovered in the printed health reports, I find that Professor Jordan has in his list 21 more deaths in 1896, 32 more in 1897, 26 more in 1898, and 27 more in 1899, 25 less in 1900, 10 less in 1901, 12 less in 1902, and 35 less in 1903, than I found in my study of the records in the mortuary office in St. Louis.

12974 MR. TODD: I move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. State whether or not you made any examination of the mortuary records of the city of St. Louis for the years 1896 to 1903, inclusive, for the purpose of determining the number of deaths attributable by the attending physician to bilious fever, enteric fever and deaths in which typhoid was assigned as the cause, but not the principal cause of deaths, and typhoid-pneumonia deaths?

MR. TODD: Object to the question for the same reasons set out at length in my previous objection.

A. I have.

MR. JEFFRIES: Q. Please state what you found in reference to deaths being caused by these diseases and the number of deaths from them?

MR. TODD: Objected to for the same reasons heretofore stated.

A. I have tabulated the deaths by the causes mentioned
in four tables. In the table which is headed "Bilious Fever
Deaths, St. Louis," the deaths occurring in these eight
12975 years are tabulated by month and year, the total number
of that year being given at the foot of the column.
I have merely tabulated the deaths caused by enteric fever in St. Louis with the total deaths from this cause per year at the foot of the respective columns and deaths in which typhoid fever was assigned as a cause of death, and which I have not included in any of the other tables I have tabulated in a similar way. The deaths from typho-pneumonia were variously recorded as "typho-pneumonia" or "pneumonia and typhoid." All of these deaths I have recorded in a similar table headed "Typho-pneumonia Deaths, St. Louis."

MR. TODD: I move to [illegible] swer for the same reasons assigned in my objection to the question.

MR. JEFFRIES [illegible] d these tables in evidence?

MR. TODD: Object to the tables for the same reasons as heretofore given.

A. They are as follows:

12976

E. E. Lochridge.

12980 MR. TODD: I move to strike out the tables for the same reasons as heretofore given.

MR. JEFFRIES: Q. Mr. Lochridge, state whether or not in your examination of the mortuary records and in obtaining the deaths reported from the various diseases heretofore referred to, you tabulated those deaths according to the results of the disease in the seven respective sanitary districts of St. Louis for the years 1896 to 1903, inclusive?

MR. TODD: I object to the question for the reasons heretofore stated.

A. I have tabulated the typhoid fever deaths in the city of St. Louis according to the residence address in which the patient died for the years mentioned.

MR. TODD: I move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. Will you present those charts and explain them and read them in evidence?

MR. TODD: Object to the question on the ground stated in my objection to the above question.

A. They are as follows:

12984 MR. TODD: I move to strike them out for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. Please exlpain these charts?

MR. TODD: Objected to for the reasons stated in my previous objection.

A. The residence at the time of death of each decedent is recorded in the first seven columns following the column giving the month when the death occurred in a residence. The total deaths thus occurring in the residence in each of the seven sanitary districts are given at the foot of each column. Following this are seven more columns in which the deaths occurring in hospitals are recorded. It will be seen that a large number of the hospitals being in the third district, that number is rather higher than any of the others. At the foot of these columns will be found the total number of deaths occurring in the respective district.

A second addition is made in the line below this in which the deaths in residences in the seven sanitary districts are added to the deaths in hospitals. This tabulation gives the actual number dieing in each of the seven sanitary districts from typhoid fever. 12985

Following these are eight more columns, the first seven representing the seven sanitary districts, and the eighth a column in which the cases from out of the city are recorded. Each square in these columns is divided by a diagonal line, and in these columns are recorded above the line the residence addresses of the patients who died in the hospitals, when such residence address is given on the mortuary records. Below this diagonal line in the same square are given the number of deaths in hospitals in that district where no residence address is given, and it was found necessary to use the district in which the hospital is located.

The first footing of these columns, the total number occurring in that district, transferred to that district from the hospital, is given above the diagonal line, while the total number of those where no residence address could be obtained and the sanitary district in which the hospital was situated was used, is recorded below the diagonal line.

In the second footing I have added to those deaths which

could be transferred to their proper residence, the total deaths in residences in the seven sanitary districts, so that the
12986 total number of typhoid fever deaths where the place of residence is known are here recorded.

In the third or last footing to these columns of the tables have been added those deaths which are recorded under the hospital district where death occurred, and which could not be transferred to a residence address.

In the three columns following, the last three on the sheet, are given first, the total deaths in the hospitals by months, with a footing at the bottom to indicate the total hospital deaths in the year. In the second column the number of these in which the record bore the note "no residence" or "no home," and in the third the total number of these hospital deaths where the residence was not given.

MR. TODD: Move to strike out the answer for the same reason heretofore given.

MR. JEFFRIES: Q. Now each of these charts which you have just described refer to each one of the various years referred to, commencing with 1896 down to 1903, inclusive?

MR. TODD: Objected to for the same reasons heretofore stated.

12987 A. Yes, sir.

MR. TODD: Move to strike out the answer for the same reasons stated in my objection to the question.

MR. JEFFRIES: Q. Mr. Lochridge, state in a general way what these tables which you have just read in evidence show?

MR. TODD: Object to the question for the reasons heretofore stated.

A. These charts show, first, that there were forty typhoid deaths in the hospitals of St. Louis during 1896, of which it was not possible to transfer the deaths to the proper residence district of the deceased in 21 cases. In 1897, 20 of the 35 hospital deaths from typhoid fever could not be referred. In 1898, 16 of the 26 could not be referred to their proper residence. In 1899, 11 of the 21 could not be thus referred, while in 1900 but 4 of the 36; 7 of the 55 in 1901; 6 of the 67 in 1902 and 3 of the 75 in 1903 could not be referred back to their residence districts.

These charts show, second, the distribution of the typhoid fever deaths in the city. If a local epidemic of typhoid 12988 fever should break out, in one part of the city, it could be noted in the months of the year of its occurrence.

Since the year 1900 the distribution throughout the seven sanitary districts has been very uniform when we consider the deaths occurring in hospitals, but referred back to their residence district. There is no district in which there was an unusual number of deaths when compared with other districts since 1900.

These charts also show the increase in the number of deaths in the hospitals and the increase in each district in each year.

MR. TODD: I move to strike out the answer for the reasons stated in my objection to the question, and also that the whole matter of districts was gone into by Professor Sedgwick in his examination in chief.

MR. JEFFRIES: Q. What do these tables that you have prepared show with reference to the distribution of typhoid deaths in St. Louis in the various districts since and including the year 1900 throughout the city?

MR. TODD: Same objection as to previous question.

A. The distribution of the typhoid deaths in the va- 12989 rious districts has been quite uniform since that time, such as might be expected if the cause for the typhoid were one which would be equally applicable to all of the citizens of the city in the way that pollution by water is applicable.

MR. TODD: Move to strike out the answer for the reasons heretofore stated.

MR. JEFFRIES: Q. Have you prepared similar charts showing the deaths from malarial fevers in St. Louis, by districts?

A. I have.

MR. TODD: I make the same objection as to previous question, and move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. Will you produce those charts and read them into the record?

MR. TODD: Same objection as to previous question.

A. I will; they are as follows:

12989 MR. TODD: I move to strike them out for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. Please explain these charts or tables that you have just read into evidence?

MR. TODD: Object to the question for the reasons heretofore stated.

A. The tables headed "Malaria, St. Louis," one table for each of the years from 1896 to 1903, inclusive, have in the first column the month of the year, in the next seven columns the deaths occurring in residences in the seven sanitary districts of the city caused by malaria or malarial fever as found by me in the records in the mortuary office.

The first footing to these columns gives the total number of malarial fever deaths in the residences in the city by districts. The second footing contains the total number of deaths referred back to the residences, from the deaths in hospitals where such residence is given. The third gives the total number of deaths which can be referred back, or occurring in the residences in the seven sanitary districts of the city.

12999 In the following columns will be found the total number of deaths in the hospitals, the number of these in each month which can be referred back to the residence district, the total number which are marked on the hospital record as having "no home" or "no residence," the total number of hospital deaths where the residence is given, and the number from out of the city which occurred in the hospitals in the city. The last column contains the totals by months and at the bottom the total deaths from malaria or malarial fever by the year.

MR. TODD: Move to strike out the answer for the reasons given in my objection to the question.

MR. JEFFRIES: Q. What conclusions do you draw from the tables with reference to malarial deaths which you have just described?

MR. TODD: Object to the question for the reasons heretofore stated.

A. The tables indicate the distribution during the year in the city and the increase in malaria from year to year between the years 1896 and 1903, which show that the distribution in these districts is not as uniform in the city as is the case of deaths from typhoid fever.

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

13000 MR. JEFFRIES: Q. State whether you have in like manner prepared tables showing the deaths from typho-malaria fever in St. Louis during the past same years?

MR. TODD: Object to the question for the reasons heretofore stated.

A. I have.

MR. TODD: Move to strike out the answer for the reasons heretofore stated.

MR. JEFFRIES: Q. Will you please present them and read them in evidence?

MR. TODD: Objected to for the reasons heretofore stated.

A. I will; they are as follows:

13009 MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. Please describe them?

MR. TODD: Objected to for the reasons heretofore stated.

A. The construction of the chart is exactly similar to that just described for the charts headed "Malaria, St. Louis."

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. State what these tables show, if anything?

MR. TODD: Object to the question for the reasons heretofore stated.

A. These tables show the total number of typho-malaria deaths in each of the seven sanitary districts for each month for the eight years mentioned, each year being on a separate chart. The distribution is here, as in the case of the malaria, less uniform than the distribution of the typhoid fever deaths.

MR. TODD: Move to strike out the answer for the reasons heretofore stated in my objection to the question.

13010 MR. JEFFRIES: Q. State whether or not you have prepared charts of the deaths from typhoid fever in the city of St. Louis for the years 1896 to 1903, inclusive, in which the deaths from this cause are tabulated according to age at the time of death and by the month of the year?

MR. TODD: Object to the question for the reasons stated in my objection to the former question.

A. I have.

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. Will you please present these charts, read them in evidence and explain them?

MR. TODD: Objected to for the reasons stated in my objection to the previous question.

A. They are as follows:

Chart No. 39.

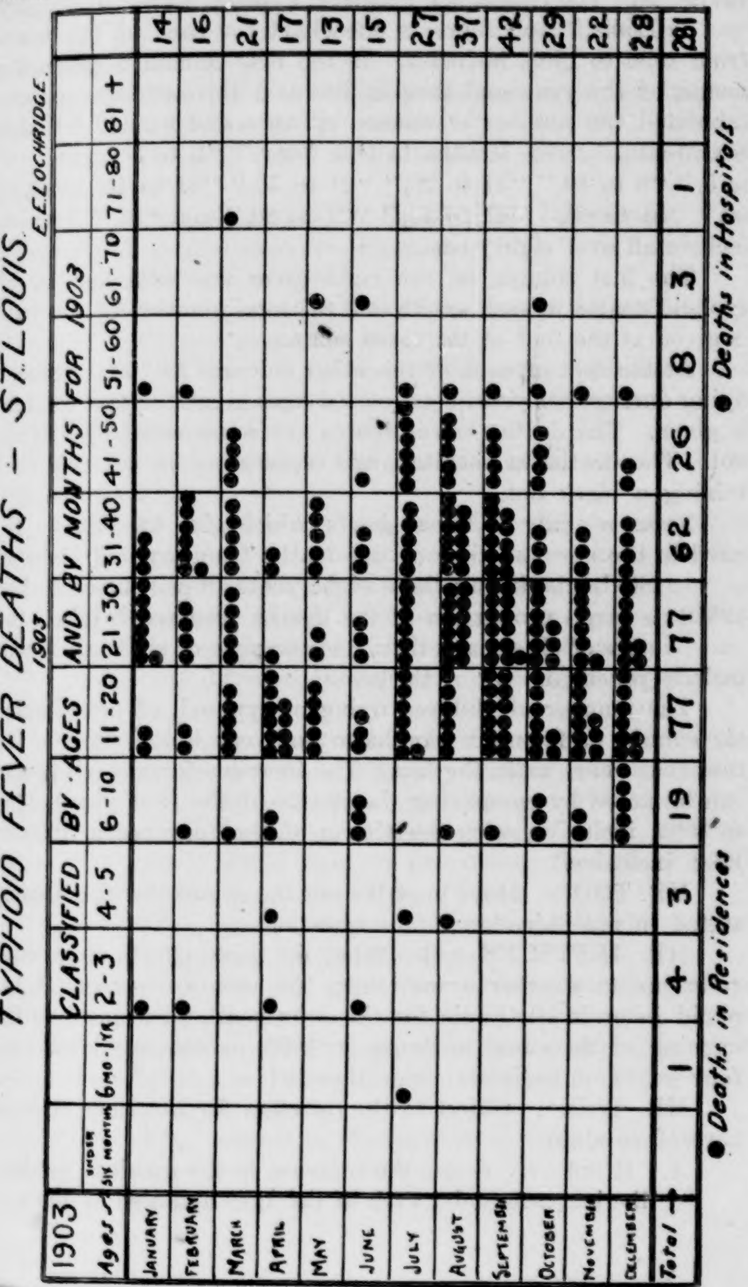
13018

Chart No. 46.



13019 A. The charts are headed "Typhoid Fever Deaths, St. Louis," and there is one chart for each of the years from 1896 to 1903, inclusive. In the first column is given the month of the year and then in the next thirteen columns are tabulated the number of deaths by ages and headed "Under Six Month." "Six Months to One Year," "2 to 3 years," "4 to 5," "6 to 10," "11 to 20," "21 to 30," "31 to 40," "41 to 50," "51 to 60," "61 to 70," "71 to 80," and "81 +" which include all over eighty-one.

The last column on the right gives the total number of typhoid deaths in each month and the total number for the year is given at the foot of the same column.

At the foot of each of the other columns the total number dying during that year, between the ages given for that column, is given. The deaths in residences are represented by a black dot. The deaths in hospitals are represented by a circle containing a black dot.

From a study of these charts, which give the data in regard to the age and time of the deaths from typhoid fever in St. Louis during these eight years, it will be seen that 13020 a large proportion of the deaths occurred between the ages of eleven and fifty, and the ages of six to sixty will include practically all of them.

The number of children dying of typhoid, of those under six months or from six months to one year is the same in the first four years as in the last. The increase for any given age can be noted by comparing the charts of the four years, 1896 to 1899, inclusive, with the charts of the four years, 1900 to 1903, inclusive.

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. What do these charts show with reference to whether or not there has been an increase in typhoid fever in St. Louis for the four years subsequent to the opening of the canal in January, 1900, as compared with the four years immediately prior thereto?

MR. TODD: Object to the question for the same reasons heretofore stated.

A. It not only shows the increase in the number, but also the increase under each of the ages and also by the sea-

13021 son of the year. This may be noted by a comparison of the number of dots for any given month and for any given age.

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. State whether or not an increase is shown?

MR. TODD: Object to the question for the reasons heretofore stated in my previous objections.

A. An increase is shown.

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. State whether or not the particular seasons of the year in which this increase is shown can be observed from the chart?

MR. TODD: Object to the question for the reasons heretofore stated.

A. The increase in any season can readily be seen from this chart, comparing, for example, any of the years since the opening of the canal with any of the years prior to the opening
of the canal. It will be noted that there is a consider-
13022 able increase during the winter months as well as a some-
what less increase, though very marked, in the summer months.

During the early years represented by these charts the number during the months of January to May, and the month of December is quite low, while since the year 1900 there has been a very marked increase of the number of deaths for this six-month period, much more in proportion than during the other six months.

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. Have you prepared similar charts of the deaths in St. Louis from remittent fever during or for the years 1896 to 1903, inclusive, in which the deaths from this cause are tabulated according to ages at the time of death and by the months of the year?

MR. TODD: Object to the question for the reasons heretofore stated.

A. I have.

MR, JEFFRIES: Q. Will you produce such charts, read them in evidence and explain them?

13023 MR. TODD: Objected to for the reasons heretofore stated in my previous objections.

A. The charts are as follows:

13024 Chart No. 47.

E. E. LOCHRIDGE

13032 A. These charts were made in the manner described for the charts headed typhoid fever deaths, St. Louis, classified by ages and by months.

It will be noted on several of these charts recording deaths from the various causes that the same black dot is used to represent a death from the cause given under the head of that chart that the dot in the circle represents a hospital death, while on some charts there is also a cross in the circle which represents a death occurring in the Missouri Pacific Hospital. This was marked in this manner for the reason that the Missouri Pacific Hopital has, during the last few years, contained during these years the record of a number of deaths of railroad men brought in from out of the city, or from their yards, and that the terms remittent, intermittent and congestive are used in their records up to about the year 1899 or 1900, and that no malarial deaths are recorded by them prior to this time, while several are recorded from malaria since that time, and the number of remittent and intermittent fever deaths has similarly declined from that hospital.

It will be noted by looking at the chart headed "Remittent Fever Deaths, St. Louis, 1896," that there are six un-
13033 der the first column who were under six months of age;
3 recorded as one year of age or under; 4 more of two or three years of age, or 9 under one year of age, or 13 under three years of age out of a total of 40 deaths occurring in that year.

There are also between the ages of 61 and 70, 5 deaths during this year, and between the ages of 71 and 80, 2 more deaths, or 7 deaths occurring of people above the age of 61 years, 20 of the 40 which do not occur between the ages of 4 and 60.

In the year following there is but one death in the first column of six months or under, and one in the column of one year of age, and but two in the third column of children of two or three years of age, or a decrease in the number of deaths of those one year of age, and under from 9 to 2, and no such corresponding increase occurs in this year in the typhoid tables already submitted.

In all of these tables the variations in the number of deaths from this cause will thus be seen to be in the column of children under three or people above 61 years of age, the numbers during the ages ordinarily considered as typhoid ages and indicated on
the typhoid charts, both before the opening and since
13034 the opening of the canal, as typhoid ages remains about
constant.

These charts also show the seasonal distribution of the remittent fever deaths.

MR. TODD: Move to strike out the answer for the reasons given in my objection to the question.

Adjourned until 8 p. m., Thursday, May 26, 1904.

13035 Room 282 Southern Hotel, St. Louis, Mo.
8:00 p. m., Thursday, May 27, 1904.

Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

E. E. LOCHRIDGE

resumed the stand for further direct examination and testified as follows:

MR. JEFFRIES: Q. Mr. Lochridge, have you prepared charts from the deaths from intermittent fever in the city of St. Louis from 1896 to 1903, inclusive, in which the deaths from this cause are tabulated according to the age at the time of death, and by the month of the year?

MR. TODD: Object to the question for the reasons heretofore stated.

A. I have.

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. Will you please present the charts, read them in evidence and state what they show?

13036 MR. TODD: Object to the question for the reasons heretofore stated.

The charts are as follows:

13045 A. These charts are headed "Intermittent Fever Deaths, St. Louis," and there is one for each year from 1896 to 1903, inclusive. They are prepared in the same way as the charts headed "Typhoid Fever Deaths, St. Louis," and show the number of deaths per month and the ages at which this death occurred, together with the total number of deaths and the age for the year and for each month in the year. The total number does not vary materially before and since the opening of the canal with the exception of the year 1899, in which there are nearly twice the number recorded for the other years.

However, in the year 1899, it will be found that there are five deaths of children under six months of age from this disease and five more between the age of six months and one year.

With this exception the number is practically the same during each of the years covered by these charts.

MR. TODD: I move to strike out the answer for the reasons stated in my objection to the question.

13046 MR. JEFFRIES: Q. I call your attention to the chart for the year 1899 and ask you to state from that chart how many deaths occurred from intermittent fever when the persons dying were within the age of three years and over the age of sixty?

MR. TODD: Objected to for the reasons heretofore stated in my objection to the previous question.

A. There were 17 deaths from intermittent fever in St. Louis in the year 1899, as shown by this chart, of persons either of or below the age of three years and of or above the age of 61. This number subtracted from the total of 25 leaves 8 of the ages when typhoid fever is most prevalent.

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. I will ask you to state from that chart how many deaths occurred from intermittent fever with patients between the ages of 11 and 30 years, at the ages when typhoid is most susceptible?

MR. TODD: Object to the question for the reasons heretofore stated.

A. There was not a single death from intermittent

13047 fever during the year 1899 of a patient between the ages of 11 and 30 years.

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. Examine the tables with reference to deaths from intermittent fever for the years mentioned and state whether or not those deaths, as a general thing, occurred during the winter season or summer season of the respective years?

MR. TODD: Object to the question for the reasons heretofore stated.

A. There are a considerable number of deaths during the summer months, as for example, in 1897 all of the deaths were between April and October, inclusive.

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. Mr. Lochridge, state whether or not you have prepared charts of a similar character upon the deaths from typho-malaria in the city of St. Louis for the years 13048 1896 to 1903, inclusive, in which the deaths from this cause are tabulated according to the age at the time of death and by the months of the year, and state whether or not these charts are prepared from the information gathered by you from the mortuary office of the health department of the city of St. Louis?

MR. TODD: Object to the question for the reasons heretofore stated.

A. I have prepared eight charts, one for each year, for the years 1896 to 1903, inclusive, with the heading "Typho-malarial Deaths, St. Louis," which have been prepared in the same way as the charts headed "Typhoid Fever Deaths, St. Louis."

All of the data for these charts was obtained from the records in the mortuary clerk's office of the department of the board of health in the city of St. Louis.

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. Will you please read these charts in evidence?

MR. TODD: Object to the question for the reasons
13049 heretofore stated.

A. They are as follows:

Mr. Todd: Move to strike out the answer for the reason
13058 heretofore stated in my objection to the question.

Mr. Jeffries: Q. State whether or not you have prepared similar charts from the evidence so obtained by you from the mortuary office of the city health department of the City of St. Louis, from malarial fevers, for the years 1896 to 1903, inclusive, in which the deaths from this cause are tabulated, according to age at the time of death, and by the months of the year?

Mr. Todd: Objected to for the reasons heretofore stated in my objection to previous questions.

A. I have.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Will you present them and read them in evidence?

Mr. Todd: Objected to for the reasons heretofore stated in my objections to previous questions.

13059 A. I will; they are as follows:

Mr. Todd: Move to strike out the charts for the reasons
13068 stated in my objection to the question.

Mr. Jeffries: Q. What do they show?

Mr. Todd: Object to the question for the reasons stated in my objection to previous questions.

A. They have been prepared in a similar manner to the charts just described, and show in the same way the deaths by months and ages and the total deaths by months and ages for the year of the charts. The period of incidence of malarial fever or malaria is shown by these charts, and quite a decided increase since the year 1900 in the ages from about 20 to 40.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. State whether or not you have prepared similar charts from the deaths from congestive fever in the city of St. Louis for the years 1896 to 1903, inclusive, obtained from the same data and tabulated according to the age and the season of the death?

Mr. Todd: Objected to for the reasons stated in my previous objection.

13069 A. I have prepared two charts to show the deaths from congestive fever at the ages mentioned on the other charts, but on account of the low number of congestive fever deaths I have plotted in one line the deaths in each year from January to March in the second line, April to June, the third line, July to September, and in the fourth October to December. The first of these charts contains the deaths from congestive fever in the four years prior to the opening of the canal. The second of these charts shows the deaths from this cause in the four years subsequent to the opening of the Chicago drainage canal.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. I will ask you to read these charts in evidence.

Mr. Todd: Object to the question for the reasons heretofore stated.

A. They are as follows:

13072 Mr. Todd: I move to strike out the charts for the reasons stated in my objection to the question.

Mr. Jeffries: Q. State whether or not you have prepared similar sharts showing the deaths from bilious fever in the city of St. Louis for the years 1896 to 1903, inclusive, upon the information obtained from the same source, said charts being tabulated according to age at time of death and the seasons of the year?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. I have prepared two charts of the bilious fever deaths in the city of St. Louis, one covering the period from 1896 to 1899, inclusive, the four years prior to the opening of the canal and the other for the four years subsequent, the years 1900 to 1903, inclusive.

These represent the deaths in the city of St. Louis by ages and seasons, from bilious fever, bilious remittent, bilious intermittent and bilious colic or occasionally called also a fever. These are designated on the charts so that one can be told from another. These charts show the total number dying at 13073 each age and in the four seasons of the year described.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Will you please read these charts in evidence?

Mr. Todd: Objected to for the reasons heretofore stated in my objection to previous questions.

A. I will; they are as follows:

13076 Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. State whether or not you have prepared a similar chart showing the deaths from enteric fever in the city of St. Louis by the ages and seasons of the year for the years 1896 to 1903, inclusive, the information for which you have obtained from the same source.

Mr. Todd: Object to the question for the reasons heretofore stated.

A. There were but six deaths from enteric fever in four years, 1896 to 1899, inclusive, and six deaths from enteric fever for the four years between 1900 and 1903, inclusive and therefore I have given but one line to a year, marking the month of death on the right hand margin. The data for this chart were obtained from the records in the office of the mortuary clerk of the board of health of the city of St. Louis.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Will you please read this chart in evidence?

13077 Mr. Todd: Object to the question for the reasons heretofore stated.

A. It is as follows:

Chart No. 83.

E. E. LOCHRIDGE.

13079 Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. State whether or not in your examination of the mortuary records of the board of health of the city of St. Louis, you found any facts bearing upon the prevalence of continued fever in the city of St. Louis during the years 1896 to 1903, inclusive?

A. During the eight years between 1896 and 1903, inclusive, there were six deaths marked continued or continuing fever, two of these occurring in the four years prior to the opening of the canal and four occurring in the four years subsequent to its opening.

There were so few of these that I did not plot them, but I will give the record of the six cases.

In 1896, 1 death, August 16th, age six months, continued fever.

In 1897, 1 death, June 2nd, age 11 years, continued fever.

In 1900, 1 death, June 8th, age three months, continued
13080 fever.

In 1902, 1 death, age three years, March 19th.

In 1903, 1 death, April 9th, age 30, marked continued fever, with a note under it, "not typhoid." Another death October 5th, 1903, age 74, marked nephrites. fever, continuing, four months.

These six are the only cases of deaths occurring, as far as I could discover from continued or continuing fever. There were no deaths marked simple continued fevers.

Mr. Todd: Object to the question for the reasons heretofore stated, and move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Mr. Lochridge, taking into consideration the deaths from typhoid fever as shown by your tables, what do these tables show with reference to the usual age at which death from this disease most usually occurs?

Mr. Todd: Object to the question for the reasons heretofore stated.

13081 A. The largest number of deaths occur between the ages of 11 and 50, and on either side of these ages that is, under 6, or over 50, there are few deaths from this cause.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. As to the season of the year, what do these tables show in a general way upon the question as to what time of the year are more deaths reported from this disease to the health department of the city of St. Louis?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. In the earlier years, notably the first four years, 1896 to 1899, inclusive, the much larger proportion of deaths occurred between the months of July and November inclusive. During the years 1901, 1902 and 1903 it will be seen that there are much larger numbers than the proportional increase in the months just referred to, during the months from January to June, and in the month of December, so that during the latter years the typhoid fever deaths are scattered pretty generally through the year, there being a few more during the summer months
13082 than during the winter months.

Mr. Todd: Move to strike out the answer for the reasons heretofore stated, in my objection to the question.

Mr. Jeffries: Q. State whether or not you have prepared any charts showing these facts?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. I have.

Mr. Jeffries: Q. Will you produce them?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. I have prepared the chart with the caption "Winter Typhoid, St. Louis," on the lower half of which are recorded the number of deaths in the months of January, February, March, April, May and December, for the years 1896 to 1903, inclusive. In the line above this tabulation is given the estimate of population found in the testimony of Messrs. Barker and Jordan.

Confirmatory of this it might be well to call attention to the fact that the United States Census estimate gives for the year 1903, 612,000, instead of 618,500, as the population for the city, but this variation would make but slight difference.

13083 In the line above the population are given the deaths per 100,000 per annum based upon the winter typhoid death rate exclusively. Above each year of actual deaths per month is plotted the deaths per 100,000 living based on the figures given below and the population given on the chart.

This death rate per 100,000 is represented by a heavy black line, and covers the years mentioned. It will be noted that in the year 1898 a dotted line leaves the heavy black line, rejoining it again in 1901. This correction was made because it was found that a local epidemic of typhoid was prevalent in the city of St. Louis at that time.

The number of deaths during this short epidemic in each of the sanitary districts was not in the proportion usually maintaining, and all of the evidence which I could obtain indicated that typhoid deaths for these months, or as far as this chart is concerned, for the months of December, 1899, and January, 1900, were in part due to this localized epidemic. For this reason the average number of deaths for the three years prior were taken and the differences between this averaged number and the recorded number was deducted and the deaths per 100,000 living, recalculated and plotted, thus showing that not consider-
13084 ing in these winter months the added deaths due to this localized epidemic, there was no increase in the winter typhoid death rate in the year 1899, and that the rise was marked in 1900 even after deducting in the same way the deaths probably due to this localized epidemic in January, 1900.

On this diagram a heavy vertical line is drawn between the spaces for the years 1899 and 1900, showing the time of the opening of the drainage canal, and the line in the space to the left of the line representing the year indicates the increase for that year. These deaths are considered per 100,000 population per annum.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Will you read this chart in evidence?

Mr. Todd: Objected to for the reasons heretofore stated in my objections.

A. I will; it is as follows:

13085 Chart No. 84.

	1896	1897	1898	1899	1900	1901	1902	1903

TOTAL DEATHS SIX MONTHS	24	37	36	43	54	56	87	109

13086 Mr. Todd: I move to strike out the chart for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Have you prepared a like chart based upon summer conditions?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. I have.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Will you please produce it, explain it and read it in evidence?

Mr. Todd: Objected to for the reasons heretofore stated.

A. The chart, with the heading "Summer Typhoid,—St. Louis," is as follows:

Chart No. 85.

	1896	1897	1898	1899	1900	1901	1902	1903
DEATHS PER 100 000	29.5	28.8	19.7	27.8	34.8	42.4	42.8	55.6
POPULATION –Jordon– –Barker–	522 225	533 762	548 590	561 510	575 238	589 315	603 736	618 516
JUNE	7	8	6	5	7	6	9	15
JULY	14	11	9	6	15	12	14	27
AUGUST	28	16	10	7	22	29	24	37
SEPTEMBER	11	17	14	15	11	25	19	42
OCTOBER	8	11	8	14	29	29	30	29
NOVEMBER	9	14	7	31	16	24	33	22
TOTAL TYPHOID DEATHS SIX MONTHS	77	77	54	78	100	125	129	172

13088 A. This chart is prepared in a similar manner to the one just described; the months considered are, June, July, August, September, October and November, or the six not considered on the other chart. The years 1896 to 1903, inclusive are plotted. The heavy black lines here represents the typhoid deaths per 100,000 population per annum, as shown in the table on the lower part of the diagram, a black vertical line between the lines representing 1899 and 1900 indicated the time of the opening of the drainage canal. The localized epidemic already referred to in connection with the winter typhoid chart began in the month of November, 1899, and I have therefore in the same manner as in the chart showing winter conditions taken the average of the total typhoid deaths for the three years prior and have deducted the difference between this number and the number recorded for the month of November, 1899, which are shown by means of a heavy dotted line thus indicating this correction for the localized epidemic on the chart. This dotted line leaves the black line indicating the total typhoid death rate of this period in 1898 and rejoins it in 1900. It will be seen that eliminating the effect of this one localized epidemic in the
13089 one month, that the typhoid death rate per 100,000 was
not materially different in 1898 and 1899, but that a sharp rise is indicated for the year 1900.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: State whether or not you have prepared a chart showing the comparisons of typhoid deaths in St. Louis for the winter and summer months prior to and since the opening of the drainage canal?

Mr. Todd: Object to the question for the reasons heretofore stated.

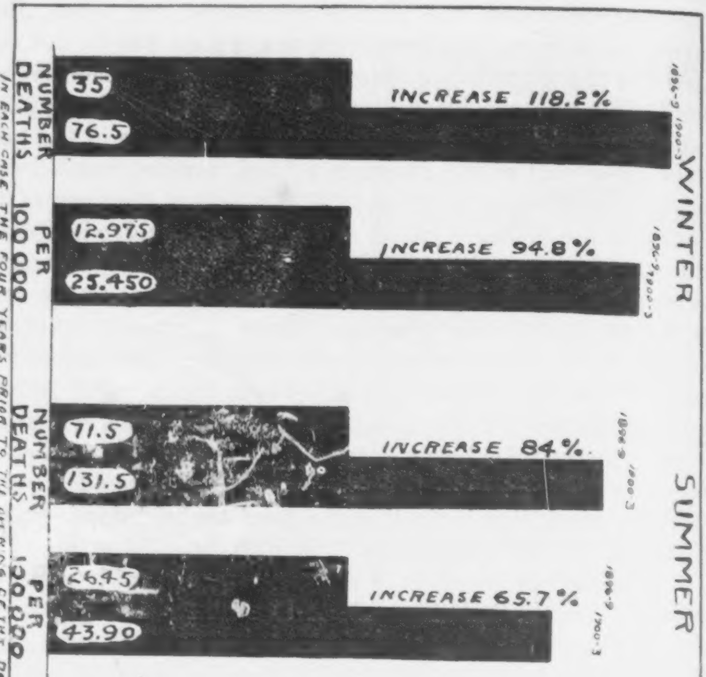
A. I have prepared such a chart.

Mr. Jeffries: Q. Will you produce, read the chart in evidence and explain it?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. The chart entitled "Comparisons of Typhoid Deaths,—St. Louis." is as follows:

13090 Chart No. 86.



13091 A. This chart shows the relative increase of the typhoid deaths and the typhoid death rate in the two seasons mentioned. The data from which these charts are prepared is all given on the last two charts just submitted. The first black staff or column on the left shows graphically, first, the average number of deaths from typhoid fever occurring during the months from January to May and in December for the years 1896 to 1899, inclusive, and also the average number of deaths occurring from typhoid fever in the city of St. Louis during these same months for the years 1900 to 1903, inclusive.

The average number for the first four years referred to was 35; for the second four years referred to was 76.5, indicating an increase in the total deaths from typhoid during the winter months referred to of 118.2 per cent.

The second staff or column indicates graphically the typhoid death rate per 100,000 per annum during the winter months referred to for the years 1896 to 1899, inclusive, and compared with the same months for the years 1900 to 1903, inclusive, the death rate per 100,000 in the first four years referred to was 12.975, and for the second period of four years 25.45 or
13092 an increase in the typhoid death rate during the winter months referred to of 94.8 per cent.

The third staff or column represents a comparison of the actual number of deaths occurring in the city of St. Louis from typhoid fever for the four years, considering the months of June to November, inclusive, prior and subsequent to the opening of the Chicago Drainage Canal, the average number of deaths occurring during these months during the years 1896 to 1899, inclusive, was 71.5 per annum. The average number of typhoid deaths occurring in the city of St. Louis for the years 1900 to 1903, inclusive, during the same summer months was 131.5, or an increase in the number of deaths during these months of 84 per cent.

The fourth staff or column from the left represents diagramatically the average death rate from typhoid fever in the city of St. Louis per 100,00 population, for these same summer months during the years of 1896 to 1899, inclusive, as compared with the average of the years 1900 to 1903, inclusive.

This average typhoid death rate during the first four years mentioned was 26.45. During the second four years it was 43.9 for the months mentioned or an increase of 65.7 per cent.

13093 The fifth staff or column from the left gives a comparison of the averages of the total number of typhoid deaths occurring in the city of St. Louis for the entire year and considering the periods of 1896 to 1899, inclusive, and the years 1900 to 1903, inclusive. The average number of deaths per annum was, prior to the opening of the canal, 106.5 per annum and 208.0 in the four years following.

The sixth and last staff or column represents a comparison of the deaths from typhoid fever per 100,000 in the years 1896 to 1899, inclusive with the years 1900 to 1903, inclusive. This average rate per 100,000 was in the first four years mentioned 19.6 and in the second four years mentioned 34.7 per 100,000, or an increase of 77.7 per cent.

In these diagrams the number or the mortality for the four years *prior*, as in the case plotted, are the same height, and the increase represented diagramatically with this as a standard so that the *relative* increase in the seasons represented may be clearly show diagramatically.

Mr. Todd: Move to strike out the answer for the reasons
13094 stated in the objection to the question.

Mr. Jeffries: Q. From what source did you get the data upon which the last three charts are based, and which you have read in evidence?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. This data was obtained by me from the records in the office of the Clerk of the Mortuary Office or Mortuary Department in the city of St. Louis. I have already read it in evidence.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Where did you get the estimates of the population of the city employed by you in preparing these charts?

Mr. Todd: Objected to for the reasons heretofore stated.

A. I have used the same estimates that were used and submitted in evidence by Dr. Barker and Professor Jordan.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Mr. Lochridge, state the character, in a general way of the examination that you made of the records in the mortuary office of the Health Department of the 13095 city of St. Louis in securing these data and the mortuary death records of the various diseases mentioned?

Mr. Todd: Object to the question for the reasons heretofore stated in my former objections.

A. I copied the date of death, the name, the age, the residence in the city, and if a death occurred in a hospital the name of the hospital and the residence address from which the case had been transferred to that hospital, the ward and sanitary district given in this record; the contributing cause of death named by the physician of every case of typhoid, typho-malaria, remittent, intermittent, congestive, continued, enteric, bilious, typho-pneumonia, or any other deaths referred to by me. In doing this I examined the cause of death of every person dying in the city of St. Louis during the eight years from 1896 to 1903, inclusive.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. From what book or books in the office of the mortuary clerk did you obtain the data? Also state how the books from which this data was obtained are made?

13096 Mr. Todd: I object to the question for the reasons already stated, and for the additional reason that this witness has not shown any familiarity with the workings of the office to which he refers and that he knows anything about how these books were made up unless he was present and saw that done himself.

A. In order that a burial certificate may be issued, the attending physician or the Coroner must bring to the mortuary office a certificate of death showing the age and cause of death in each case. These certificates contain the age at death, also quite frequently the duration of the illness, the contributing cause and any remarks of the physicians and the residence and place of death of the deceased.

The data from these certificates is then copied into large books which are so ruled that each part of the data referred to is recorded in a separate column, this record being made by an assistant. Every death is then checked by the mortuary clerk. These books are then regarded by them as the official records of these deaths and any certified copies of death made to insurance companies or others are made from these books.

13097 These books are all kept with great care, in a large vault.

Mr. Todd: I move to strike out the answer for the reasons assigned in the objection to the question and for the additional reason that this witness is not competent to pass upon whether a book is a public record, and the method of certifying said records for different uses, and for the further reason that he is not competent to pass upon whether the books kept in this office are public records and entitled to the force of such.

Mr. Jeffries: Q. These books about which you have spoken in your last answer are the only mortality records in the mortuary office of the board of health in the city of St. Louis are they not, from which the data which you obtained can be secured?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. I believe they are. I was so informed.

Mr. Todd: Move to strike out the answer for the same reasons contained in my objection to the question.

13098 Mr. Jeffries: Q. State whether or not the officer in charge of these books permits them to be taken from the office?

Mr. Todd: Object to the question for the reason that a subpoena from this court will produce any public record in the city of St. Louis, and it is not competent for this witness to pass judgment upon questions of that character.

A. He will not.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. State whether or not those records, as observed by you, while you were working upon them, were not in daily use?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. Those records were in daily use.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. State whether or not you made inquiry as to whether and how these books may be taken out of the mortuary office, if at all?

Mr. Todd: Object to the question for the reasons already 13099 stated in my previous objection, and for the additional reason that what any one told to him is hearsay and not competent evidence.

A. I made such inquiry and was informed by the Clerk of the mortuary office that such records might not be taken by any one from the office, and that if it was necessary to use them at any time outside, permission must be secured from the Commissioner and subpoena issued and a regular member of the staff must always accompany them.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: I will state for the benefit of the Court I would be very glad, indeed, to introduce this book in evidence, but on account of its public importance I am unable to do so, on account of it being absolutely necessary that it remain in the archives of the mortuary office.

I will also state to the counsel for the defendants that if he desires I will have this book produced before him, subject to his inspection, if it is possible to do so.

13100 Mr. Todd: In reply will state that counsel for the defendant desires nothing as complainant has the burden of making out their own case according to legal evidence.

Mr. Jeffries: Q. How many of those books are there, as well as you remember?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. I should think 11 or 12.

Mr. Todd: I move to strike out the answer for the reasons heretofore stated in my objection to the question.

Mr. Jeffries: Q. How large are they, about how many pages?

Mr. Todd: Objected to for the reasons heretofore stated in my objections to former question.

A. Why several hundred pages. They are perhaps four inches thick and the height of the page over two feet.

Mr. Todd: Move to strike out the answer for the reason stated in my objection to the question.

Mr. Jeffries: Q. Have you your original transcript from 13101 the record, showing the data which you have introduced in evidence, together with the name of the decedent?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. I have.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Will you present those?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. I will.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: I desire to offer those as complainant's rebuttal exhibit for identification, which said exhibits are produced and marked by the commissioner, complainant's rebuttal exhibit 1 for identification.

Mr. Jeffries: Q. Mr. Lochridge, will you compare the deaths from remittent fever in the city of St. Louis with those of typhoid fever during the periods referred to by you in your testimony and upon which your tables and charts are 13102 based?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. Deaths from typhoid fever in the year 1896 will be seen to lie quite well between the ages of 6 and 60, while 22, or considerably over fifty per cent. of the remittent fever deaths for this same year are either younger or older than the ages mentioned, or in other words, are either infants or old people.

In the year 1897 there were 11 less deaths from remittent fever than there were from this same cause in 1896, but that loss might be considered as entirely among the very young children, and it can be seen by referring to the typhoid deaths for 1897 that not one of these has been added to the death rate from typhoid fever, or in other words there could have been no transfer to typhoid fever due to better diagnosis. If the change in the annual number of remittent fever deaths be due to such better diagnosis, these deaths have been referred to some other disease than typhoid fever. A study of the tables through all the following years from remittent fever will show this same variation, the variation being in the number dying under the age of six years, the number of deaths remaining practically the same during the ages in which the mass of the typhoid fever deaths occur.

Mr. Todd: Move to strike out the answer for the rea-
13103 sons stated in my objection to the question.

Mr. Jeffries: Q. Will you compare the deaths from intermittent fever in the city of St. Louis with those of typhoid as shown upon the charts and plats as compiled by you?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. In the year 1896 there were 12 deaths from intermittent fever and in the year 1897 there were 12, but these may be seen to have been in entirely different ages, the same variation in the number of deaths in children under the age of 1, particularly, and in some cases under the age of 6, being quite apparent. This is noticed quite effectively in the increase in 1899 of the number of deaths from intermittent fever to 25, the increase being entirely in these younger ages.

The next year, or the year 1900, there were but three deaths from intermittent fever of people 20 years of age or younger, while if we consider the deaths from typhoid fever there is no marked increase in this age and there were no deaths from typhoid fever in that year recorded in the first two columns, those of six months of age and under and those of one year, so that
the decrease in the number of intermittent fever deaths
13104 for the year 1899, when there were 25, and the year 1900,
when there were 10, has not been brought about by transfer of these deaths to the typhoid group. In the other ages the intermittent and typhoid deaths are practically the same respectively, in each of the seven years.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Will you compare the deaths from typho-malaria fever in the city of St. Louis with those of typhoid?

Mr. Todd: Objected to for the reasons stated in my previous objection.

A. The deaths from typho-malaria follow more nearly the age periods of the typhoid fever than do those of either the intermittent or the remittent fevers. The number of deaths from typho-malaria per year is practically the same during the four years prior to the opening of the canal and the four years subsequent. A greater variation in the age at the time of death occurs in the typho-malaria group than in the typhoid group, the numbers remaining proportionately the same for the respective years.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

13105 Mr. Jeffries: Q. Will you compare the deaths from malaria fever in the city of St. Louis with those of typhoid for the respective years, as shown on your charts?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. The deaths from malaria and malarial fever will be seen to be distributed about the same proportionately over the various ages in the different years plotted. There has been a marked increase in malaria and malarial fevers during the past few years. It will be noted that there are about the same number of deaths in the younger ages from malaria or malarial fever during these years and the number of older people is proportionately considerably higher than the mortality in these ages from typhoid fever.

Mr. Todd: Move to strike out the answer for the reasons stated in my objections heretofore.

Mr. Jeffries: Q. Please compare the deaths from congestive fever in the city of St. Louis with those of typhoid during the respective years as shown upon your tables?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. Here again we find the large variation occurring 13106 among those under the ages of six months, one year and two and three, the variation being about the same as in the case of remittent and intermittent fevers. The year 1896 was much higher than any of the other years, although 1897 was also high. It will be noted however, looking at the list in 1896 that 13 of the cases of the congestive fever deaths were under the age of five years, ten of those under one year, and as pointed out before there has been no increase in these ages in the latter period, in the typhoid fever list. With the exception of two years when the congestive fever list was low, the variation was due to the deaths under these younger ages or of quite old people.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. Will you compare the deaths from bilious fever in the city of St. Louis with those of typhoid as shown by your charts?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. The number of deaths from bilious fever is in all cases without any variation in the number, being either 13107 in the younger ages or in the older ages, and as mentioned before there has been no increase in the typhoid fever deaths in these ages to correspond with the decline in the bilious fever deaths of those ages. The bilious fever has been considered because no record of it was found in the printed report, and it was thought that possibly it might have been included in the group of "fevers" referred to in this case.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Based upon the increased death rate from typhoid fever in St. Louis since January, 1900, as compared with the typhoid mortality prior to January, 1900, in the city of St. Louis, state whether or not you have made any estimates as to what would be the probable influx of people coming to St. Louis on account of the construction of the World's Fair in the last few years, assuming that any considerable portion of such increase in typhoid in St. Louis was brought about by reason of the influx?

A. Yes sir, I have made such a calculation.

Q. What is it?

13108 A. The highest mortality from typhoid fever per 100,000 in any of the four years prior to January 1, 1900, was 21.6 in the year 1899. This is the total typhoid mortality per 100,000 for that year, including the localized epidemic of that year, or 21.6 was the typhoid death rate for 1899, that being the highest of any time of any year during the four prior years.

On the basis that such influx of those connected with the construction of the Fair or attendance at the Fair would increase the typhoid death rate of the city, I have calculated the population that would be required in order that 21.6 should be the death rate per 100,000 for each of the six years since that time.

In 1900 there were 154 deaths according to my figures from typhoid fever in the city of St. Louis. This would indicate a population of 714,000, or an influx of 139,000 being the difference between 714,000 and 575,000, the population of that year. In 1901 there were 181 deaths from typhoid fever in the city which, considering a death rate of 21.6 per 100,000, would indicate a population of 840,000 or an addition of 251,000 people.

Considering the same death rate from typhoid fever, the 13109 total of 216 deaths from this cause in 1902 would indicate a population of 1,000,000 people or an increase of 395,000. With 281 deaths from typhoid fever in 1903, in order to make the death rate of 21.6 per 100,000 would require a population of 1,300,000, which would require an increase in the population above the population of St. Louis estimated by Professor Jordan of 681,500 people, or an increase of more than the entire present population of the city.

Q. State what conclusions you draw from that estimate, basing the population for 1903 upon Professor Jordan's figures as to whether the population in the city of St. Louis has increased proportionately with the increase of deaths from typhoid fever?

A. On the basis of Professor Jordan's estimates of the population in the city in the year 1903 of 618,500 which is but something less than 60,000 increase in population over 1899, it will be seen that the increase in typhoid has been much more rapid and that it can not be ascribed to any considerable extent to the addition of these or others who may have been in the city during this time.

ADJOURNED until 10:00 a. m., Friday, May 28, 1904.

13110 Room 282 Southern Hotel, St. Louis, Mo. 10:00 a. m., Friday, May 28, 1904. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

E. E. LOCHRIDGE

resumed the stand for further direct examination by Mr. Jeffries, and testified as follows:

Q. Can this comparison be shown in any other way?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. It can. Considering the figures given by Professor Jordan for the population of St. Louis, and supposing that the typhoid death rate per 100,000 had remained at 21.6, this population at this rate would have indicated about 130 deaths from typhoid for the year 1903. The actual number of deaths was 281. It can thus be seen that the increase in the typhoid death rate is more than double in 1903 what it was in 1899, while the population has increased but little over ten per cent.

Mr. Todd: Move to strike out the answer for the reasons stated in the objection to the question.

13111 Mr. Jeffries: Q. Mr. Lochridge, have you read the testimony of Professor Jordan and Dr. Zeit and Professor Russell in this case?

A. I have.

Mr. Todd: Move to strike out the answer for the reasons given in my objection to the question.

Mr. Jeffries: Q. Are you familiar with their experiments which are known in the record in this case as their parchment sac experiments upon the longevity of the typhoid bacillus in the waters of the canal and the Illinois Rivers?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. I am.

Mr. Todd: Move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. State whether or not in your opinion the results of these experiments represent or simulate natural conditions?

A. I do not think they do.

Q. Why?

13112 Mr. Todd: Object to the question for the reasons heretofore stated.

A. In the first place any sac lodged at one place will receive the influence, if the osmotic conditions are as perfect as is supposed, of sewage which is fresher continually than would be in contact with similar germs passing down the stream. The actual influence, if there is any, of the sac itself is not known. The results vary to some extent from earlier results obtained by various bacteriologists on this same point. There were but three of the series of Professor Jordan's experiments in the drainage canal at either Robey Street or at Lockport in which the typhoid organisms were found at all *after* 10 minutes had elapsed, with the exception of one case where it was found ten minutes after inoculation. Of these three cases one is a recorded instance of its occurence on the 10th day. This has been attributed, by Professor Jordan, to the fact that bacteria, and especially the typhoid bacteria may be dried against the neck or some part of the sac, and thus be subjected to conditions of greater longevity. This is a possible explanation for this, but there seemed to me to be other explanations. It is a fact, recognized in general, I believe, by bacteriologists that of several forms 13113 of micro-organisms in the water that one of these forms will apparently mask others, as in the case of experiments with colon and streptococci.

In the earlier periods the colon masks the streptococci so that but few or none are seen. While later the streptococci develop much more abundantly and to an extent over growing the coli. Later, however, the coli may again appear. Considering this principle it may have been impossible on any of the earlier determinations to have detected the typhoid, although there is no conclusive proof that they were of necessity absent up to the time of this appearance on the tenth day, and the three typhoid colonies found may be ascribed to the fact that their presence was masked before that date. In regard to the other determinations of Professor Jordan, showing that the typhoid were certainly alive in two cases after the second day, indicates that this germ will live at least this long, but I do not believe that it necessarily shows that they do not live longer.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

Mr. Jeffries: Q. State whether or not in the parchment sacs in which the fecal matter and the urine of typhoid patients was deposited by Professor Jordan, that the typhoid germs might not have been encased in particles of fecal matter and thus preserved? 13114

A. It seems to me quite probable that they may have been thus encased and in this way have lived for a considerable period of time.

Q. State whether or not these experiments maintained natural conditions in the waters of the canal and the Illinois River at all times of the year, and all seasons of the year?

A. I do not believe that they do. The experiments were attempted at one season of the year, I believe during the fall, and for this reason I do not believe that they simulate all conditions of flow and the conditions prevalent in all seasons of the year.

Q. State whether or not you have read the evidence of Professor Jordan and Professor Burrill upon the colon tests and experiments made by them and introduced in evidence?

A. I have.

Q. State whether or not these tests disclose an elimination of the coli from the waters of the Illinois River? Also your reasons for the answer?

A. They do not show by any means the total elimination. Of course there is a reduction, but there is no point reached where there is an elimination of the colon as is shown directly from the tables. These coli determinations are always subject

to a good many conditions, especially the presence of
13115 streptococci or perhaps even other bacteria present in
the water. These very frequently mask the coli so that any reaction of the coli is not given. In a river water it quite frequently happens that two samples of equal volume, from the same source, will one give the positive, the other the negative reaction for coli, for this reason; so that I do not believe that a negative reaction by any means is indicative of the absence of the coli, especially when it is frequently found in other samples from this same source.

Q. Mr. Lochridge, in your work upon water sanitation, state whether or not you have been engaged in the work of testing the presence of coli and typhoid bacilli?

A. I have made a great many such determinations.

Q. State whether or not you are acquainted with what is known as the Widal test?

A. I am.

Q. Have you had any experience with this test or in making this test?

A. I have frequently made the test in the laboratory and in the class, and have since that time, on several occasions made this test in the office of a city board of health.

Q. State what in your opinion the effect of the use of
13116 this test, the Widal test, has upon the typhoid mortality
records of a city?

A. I do not see any indication that it does materially change them at all. There are some reasons for believing that it has reduced the number of typhoid fever deaths, for the reason that it throws out many deaths of fevers with somewhat similar symptoms which might have been in the earlier stages originally diagnosed as typhoid.

Q. Upon your examination of the records of the mortuary office of the city of St. Louis, prior to and subsequent to the use of the Widal test, what is your opinion as to the effect of this test upon the typhoid mortality at St. Louis?

Mr. Todd: Object to the question for the reason it is incompetent, irrelevant and immaterial and not based upon any facts legally established in evidence.

A. The use of the Widal reaction was begun in the city of St. Louis in the early part of 1897. I do not see that any considerable numbers have been either transferred to or taken from the typhoid list for the city of St. Louis on account of the adoption of the Widal test.

Mr. Todd: I move to strike out the answer for the reasons stated in my objection to the question.

13117 Mr. Jeffries: Q. State whether or not, Mr. Lochridge, from the tables which you have introduced and the charts which you have prepared and read in evidence, and from your examination of the records of the mortuary office in the Board of Health of the city of St. Louis there has been any considerable number of deaths transferred from remittent, intermittent, typho-malaria, malaria, congestive and continued fevers to those designated as deaths from typhoid fever since the opening of the canal in January, 1900, as compared to the four years preceding?

Mr. Todd: Object to the question for the reasons heretofore stated.

A. I do not believe that any considerable number of deaths have been classed as typhoid since the opening of the drainage canal, which without the use of the Widal reaction would have been placed in the column entitled remittent, intermittent, typho-malaria, congestive and continued fevers. The variation in the number of the people dying from the fevers I have diagrammed has been of people of ages when there are the least number of deaths from fevers and there are more deaths of those at the age of typhoid susceptibility, in the years since 1900 than at any other time during the eight years examined.

Mr. Todd: I move to strike out the answer for the reasons in addition to the ones already assigned that this witness has not qualified as an expert upon the technical diag-
13118 nosis of fevers and is not competent to pass an opinion upon the subject.

CROSS-EXAMINATION, by Mr. Todd:

Q. In preparing the tables which you have introduced in evidence, were you assisted in going through the entire records by any official of the office of the health department of the city of St. Louis, checking up the deaths with you, or did you do it alone?

Mr. Jeffries: Objected to as immaterial.

A. All the work was done in the office of Mr. M. Smyth, the clerk of the Mortuary office. He looked over all that I had copied, and I asked him to check certain places which he did, finding the number the same.

Mr. Todd: I move to strike out the answer as not responsive.

Q. Question read.

Mr. Jeffries: I suggest that the answer is responsive to the question.

13119 A. I did every bit of the work myself and was assisted only in the way mentioned.

Mr. Todd: I move to strike out all of the evidence of this witness in regard to the records of the mortuary office of the board of health of the city of St. Louis, the tables, charts, deductions and conclusions drawn therefrom, for the following reasons:

That the public records of the mortuary office if admissable at all are the best evidence. That it is not the proper way to prove a public record. That the testimony of this witness is not proper and competent evidence to impeach the official published reports of the health commissioner of the St. Louis Board of Health, published by authority of said board, for the reason that the published records of the mortuary office if competent to impeach the authorized published reports of the health department or health commissioner of St. Louis can not be proven in the manner as testified to by this witness, but that the public records themselves are the best evidence and can not be proven in this manner. That it is improper at this time for plaintiff to attempt to impeach the official reports of the 13120 health commissioner of the city of St. Louis, which report was relied upon and testified from in the evidence in chief by the complainant's witnesses and made a part of the evidence in chief in this case and is therefore not proper rebuttal and is incompetent and improper evidence. That it is not proper rebuttal after being considered and gone into in chief as the defendants had the right to rely upon the official reports of

the Health Commissioner of the city of St. Louis, published by the authority of the board of health of St. Louis and introduced in evidence by complainant, and if said reports were incorrect, inaccurate and unreliable it was the duty of complainant to make such proof in chief and not wait until defendants had rested their case to introduce such improper and incompetent evidence for the purpose of impeaching the official reports of the health commissioner of the city of St. Louis or of proving the public records of the St. Louis health department in the manner attempted to be done by the testimony of this witness. The entire testimony of this witness in regard to the public records of the board of health of St. Louis being incompetent, all conclusions, charts, deductions and opinions are therefore incompetent, and not proper rebuttal for the reason that the alleged facts and alleged records which are the basis of such tables, charts, deductions and opinions not being legally proven
13121 and legally established vitiate any charts, tables, deductions and conclusions of this witness and not being proper rebuttal evidence is incompetent, irrelevant and immaterial.

Mr. Jeffries: In answer to the objection. I will state to the Court that counsel for defendants, together with the witnesses Dr. Barker, Professor Jordan and Dr. Thayer have themselves impeached the validity and accuracy and correctness of the published report of the city board of health.

I desire to say further that at the time complainant introduced its evidence as stated a few days ago, no attempt upon the part of complainant was made to use the mortality record upon any disease other than typhoid fever, complainant believing at that time that deaths from no other disease would be brought into this controversy or had any part in it. Having previously verified the record with the published report upon the question as to the number of deaths from typhoid during the various years, and that after complainants had closed their testimony, the defense saw proper to inject deaths from remittent, intermittent, typho-malaria, congestive, and con-
13122 tinued fever in evidence with a view of showing a greater number of deaths from those diseases in St. Louis than had actually occurred, it was but natural for counsel to

have the original record as made up by the mortuary officers from the death certificates of the physicians upon the nondescript and other diseases so referred to and that after defendants had closed the taking of its testimony these compilations were employed by this witness in due form with a view that the court, in passing judgment upon this controversy, may have all the information obtainable and have it accurate and correct.

Now, as to the introduction of the original records, I desire to state, as I stated last evening, that it is impossible to introduce them in evidence, and that if they were introduced and placed before the court, it would be necessary for the court perhaps to spend months in making the determinations themselves because of the fact that all deaths from any character and from all diseases are recorded in these books, and we have therefore secured this data in the most practical and best manner possible.

13123 Mr. Todd: In regard to counsel's statement, the argument of convenience does not obviate the legal objections made by defendants to the admissibility of the testimony, and defendants have a right to demand that evidence in order to be competent must be legal.

Mr. Jeffries: Mr. Commissioner, will you issue a subpoena duces tecum for Mr. M. Smyth, mortuary clerk, for the mortuary records containing the deaths from typhoid, typho-malaria, intermittent, remittent, congestive, simple continued and bilious fevers and malarial fevers, for the years 1896 to 1903, inclusive.

Mr. Todd: Q. When did you complete your studies in bacteriology, Mr. Lochridge?

A. I do not know that such studies are ever completed. I have taken work under Professor Smith of Beloit, dating back as far as 1897. I completed the work in the Chicago University in 1900 under Dr. H. E. Daviess who was at that time Dr. Jordan's principal assistant.

Q. Have you ever made any experiments on your own account with the parchment, celloidin and agar blocks?

A. I have not.

13124 Q. Have you ever conducted independently and on your own account any experiments upon the longevity of the typhoid fever bacilli under natural conditions?

A. No sir.

Q. Have you made a study of the diagnosis of fevers?

A. No sir.

Q. Have you ever made the Widal test for the purpose of diagnosing fevers?

A. I have.

Q. Are you acquainted with the number of doctors in the city of St. Louis who employ the Widal test?

A. I do not know the number that employ that test.

Q. Have you any means of knowing anything about the number of doctors in St. Louis that employ that test?

A. I do not know where the records could be obtained in that line.

Q. You are not acquainted in St. Louis among the medical fraternity, except those who have testified in this case, are you?

A. No sir.

ELBERT E. LOCHRIDGE.

13125 PROF. WILLIAM T. SEDGWICK,

recalled as a witness in rebuttal by complainant, having been duly sworn by the Commissioner in his examination in chief, was examined by Mr. Jeffries, and testified as follows:

Q. Professor Sedgwick, you have testified in this case before, have you not, for complainant?

A. I have.

Q. Professor, I will ask you to explain why you have used in your testimony in this case the percentage mortality basis in determining the increase or decrease of typhoid fever death rate in the city of St. Louis?

Mr. Todd: Object to the question for the reason it is not rebuttal, as the Professor was the first witness in this case who introduced the mortality percentage method, and at the time of its introduction he went fully in his explanation into why he used it, and it is merely repetition and not rebuttal and therefore incompetent, irrelevant and immaterial.

A. I think I stated briefly when testifying in chief my reasons for using the percentage mortality basis, but inasmuch as witnesses for the defendants have criticized this method, I de-

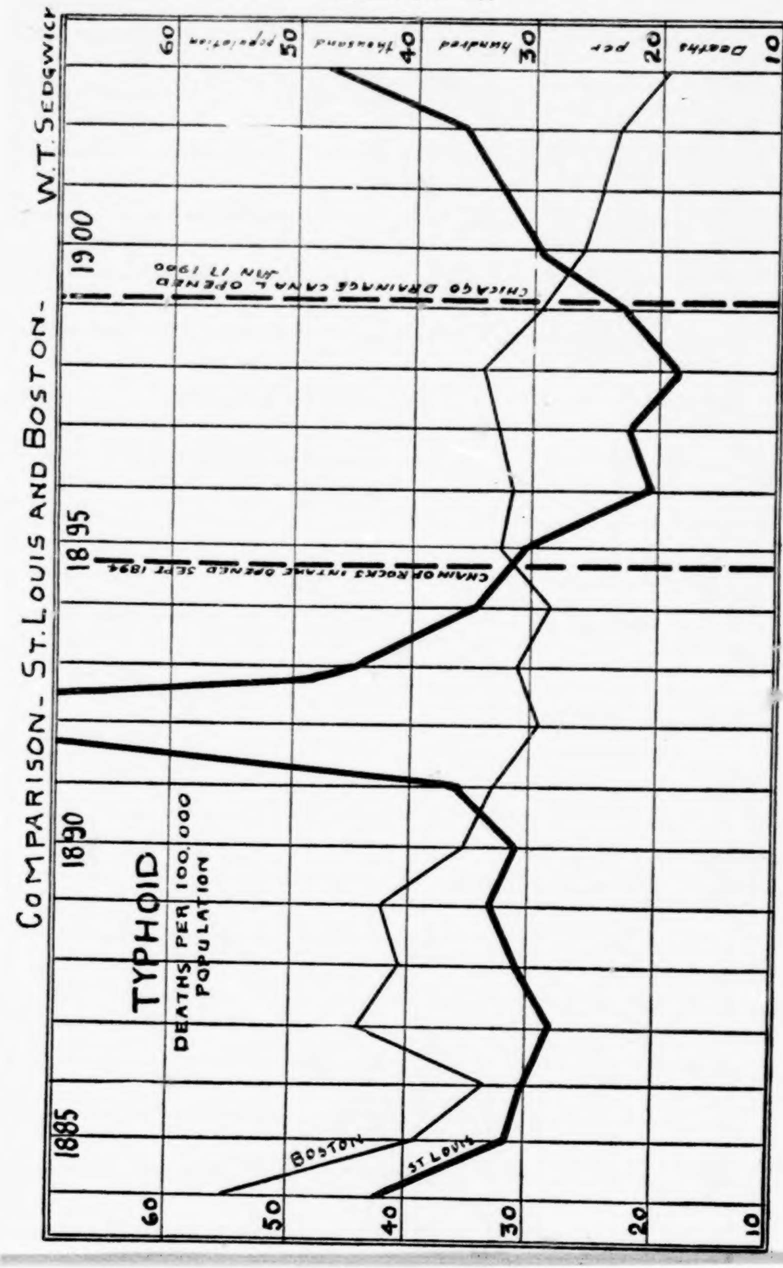
sire to state further my reasons and to show by two sim-
13126 ple charts that in the case of two cities of closely sim-
ilar population, St. Louis and Boston, this method yields results similar to those which would be obtained by the deaths per 100,000 basis, that is, the basis of deaths to population. Both methods are in common use and it is to a considerable extent a matter of choice or taste whether one shall employ one method or the other. In favor of the percentage mortality method is the fact that it eliminates from the problem altogether the question of population, and inasmuch as population in many communities, especially between census years, is a most uncertain matter, I personally make frequent use of the percentage mortality method.

On the other hand there is no doubt that under certain circumstances the other method furnishes more instructive and sometimes more accurate results. This is particularly true when the population is accurately known.

In order, however, to show that in the present case the method of percentage mortality, that is to say the proportion of the typhoid deaths to the total number of deaths is neither inaccurate nor misleading, I have prepared the charts above referred to. One of these, entitled "Typhoid percentage to total
mortality" is constructed upon the basis which I em-
13127 ployed in my testimony in chief and upon this chart I
have indicated not only the typhoid fever death rate computed in this way for the city of St. Louis, but also for that of Boston, a city of almost exactly the same size.

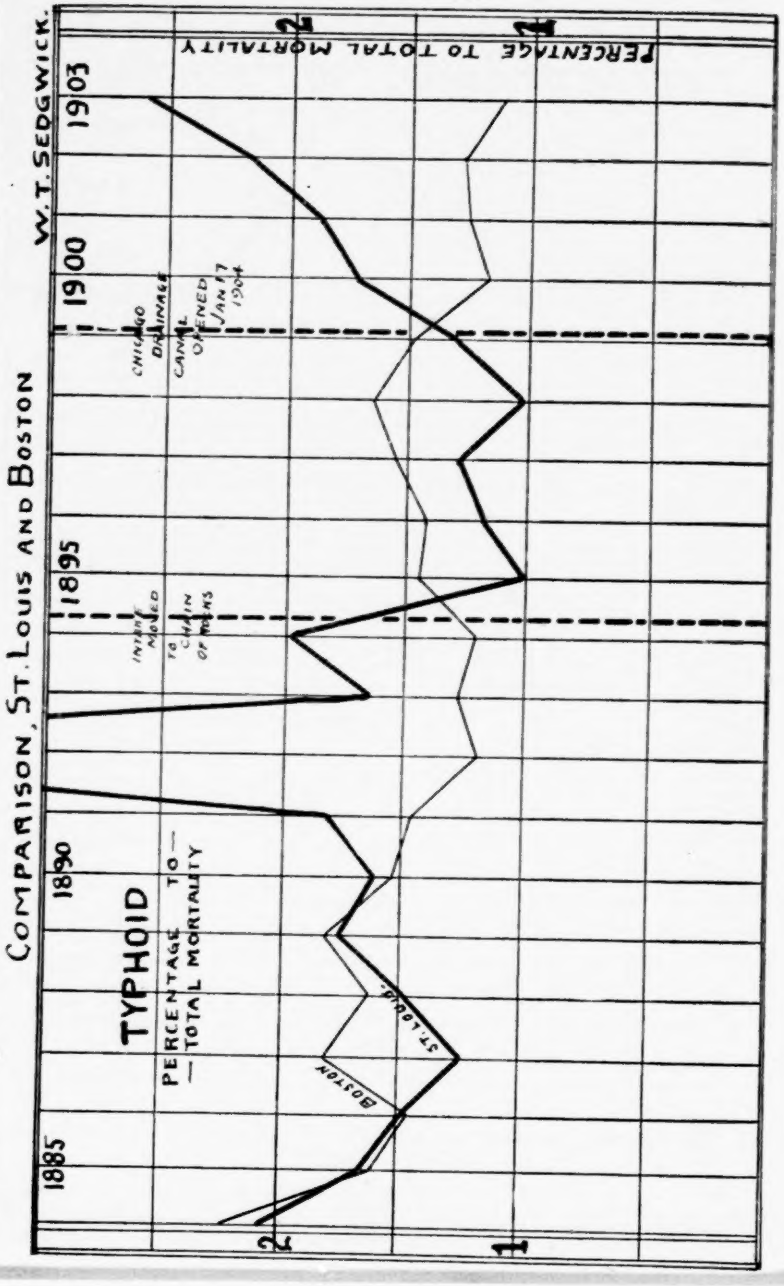
The second chart, entitled "Typhoid Death per 100,000 Population ." is constructed upon the other plan and represents the deaths from typhoid fever in St. Louis and in Boston for the same years covered by the first diagram, namely the ten years, 1884 to 1894. These charts show, I think, clearly the fact that no misleading conclusion could have been drawn from my original testimony, for both demonstrate clearly and to the same effect the essential facts as testified to at that time. These charts are as follows:

13128 Chart No. 87.



13129

Chart No. 88.



13130 MR. TODD: I move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. In the testimony of defendants, taken on February 3rd, 1904, Professor Jordan was asked the following question: "Professor Sedgwick stated * * * * the River Commissioners of Great Britain, in a report published by them in 1874, stated that there is no river in England long enough to purify itself from any sewage admitted to it even at its source. That stands as one of the axioms of sanitary science today, that those River Commissioners, in 1874 I think it was, made the statement that there is no river in the United Kingdom, I think they said, long enough to purify itself of any sewage introduced into it, introduced at its source and of course some of the rivers of the United Kingdom are very long." Professor Jordan stated that he was not able to find this quotation, saying that the closest that he could find to it was the following: "It will be safe to infer that from the above results there is no river in the United Kingdom long enough to effect the destruction of sewage by oxidation." Professor Jordan was further asked "What 13131 is the difference between the expression 'to effect the destruction of sewage by oxidation' and the expression 'to purify itself of any sewage introduced into it at its source.' "

Now, Professor Sedgwick, I will ask you to state whether or not the quotation as you gave it from memory or the version suggested by Professor Jordan is the nearer the true quotation and was essentially correct?

A. I think that the quotation which I made from memory was nearer the original, which I will now read from the report referred to by myself, and I presume by Professor Jordan, namely the Sixth Report of the Rivers Pollution Commission appointed in 1868, which inquired into the best means of preventing the pollution of rivers. This report was published in London in 1874 as one of the British Blue Books, and on page 427 occurs the statement to which I referred, as follows:

"There is no river in the United Kingdom long enough to secure the oxidation and destruction of any sewage which may be discharged into it, even at its source."

I may say that I am not surprised that Professor Jor-

13132 dan had difficulty in discovering this precise quotation, inasmuch as the book is a large one and is not at all well arranged. I may say further that the popular version of the statement made by the Commissioners is simply that "there is no river in England long enough to purify itself." It is easy to see how this shorter version has arisen, and if it were simply made to run "There is no river in the United Kingdom long enough to purify itself" I believe that it would substantially represent the true doctrine of sanitary science today.

Q. Professor Sedgwick, have you examined the testimony of Professor Jordan, Dr. Zeit and Professor Russell concerning their experiments upon the longevity of the typhoid germs in parchment and celloidin sacs and agar blocks suspended in Lake Michigan, the Chicago river, the drainage canal and the Illinois river, and all other similar experiments made by these gentlemen and introduced in evidence?

A. I have.

Q. State whether or not you are able from the determinations made by them in the above connection to formulate an opinion as to the longevity of typhoid organisms con-
13133 tained in these waters?

A. No, I should not be able either to form or to formulate a comprehensive opinion from these experiments alone. It is clear of course that, as shown in these experiments, the germs survive for certain lengths of time, but I should be unable to conclude from the experiments that under different conditions typhoid fever germs might not survive for longer times. The experiments appear to me to have been very ingenious and interesting, but not by any means conclusive upon the whole subject of the longevity of typhoid fever germs in moving bodies of sewage or water.

Q. State whether or not in your opinion these experiments just referred to simulate natural conditions in the water?

A. Undoubtedly they were devised as far as possible to do this, but in a great deal of experimental work the result of the experimenter falls short of his endeavors. I do not see how it is possible in the present state of bacteriology to devise any series of experiments which shall accurately and completely imitate the infinitely various conditions of running streams, and particularly streams such as the Chicago river, the Chicago

drainage canal and the Illinois river, subject as these are, to
an endless variety of alterations, in their physical,
13134 chemical and bacteriological conditions.

For example, these experiments were carried on in cold weather I believe, but even if they had been carried on for an entire year, under all actual variations and conditions, they would still in my judgment have been incomplete for the reason that in other years under other conditions organisms as sensitive as typhoid fever microbes are, might have encountered environments which would have materially altered the results. Besides, it seems to me that the conclusions arrived at by these able investigators indicate a shortness of life of the typhoid fever germs which is not in harmony with the longevity naturally deducible from the experience of mankind with epidemics due to typhoid infected waters, and while evidence of this kind is hard to reduce to a strictly scientific basis it has, I believe, nevertheless great value, for the reason that it is the outcome of the experience of the race.

Furthermore, the results of these experiments, broadly speaking, indicate a considerably shorter period of life for the typhoid fever germs in sewage and water than has been found by the majority of previous investigators. My own opinion is that a greater number of experiments, conducted for a longer
time, and under different conditions, would not fail to
13135 show that typhoid fever germs may, and do, live in
sewage and running streams a very much longer time
than was found in these particular experiments.

Q. In what particular way did these experiments fail to represent true natural conditions?

A. I should not say that these experiments failed to represent natural conditions, any further than many experiments must necessarily fail to imitate natural conditions. I mean by that, that these experiments were undoubtedly well planned and well conducted, but it is easy to suggest a great number of points in which they do nevertheless fail, the principal failure being to duplicate all the various conditions of the running stream. Some other matters have already been mentioned by witnesses for complainant in rebuttal, such, for example, as the fact that the germs in the several experiments were anchored, so to speak, at fixed points, instead of being allowed to float

down the stream with a particular body of water. Anyone can readily see that this is an unnatural condition, especially in the case of the Drainage Canal, and the Chicago and Illinois rivers, for the reason that the chemical composition of these bodies of sewage and water is subject to frequent changes. If, for example, the waste from a large industrial establishment
13136 shoudl be turned into the Chicago river at any particular moment the water which received it would vary materially in chemical composition from the water just preceding and just following it. For this reason sacks or blocks at anchor are probably exposed to a greater variety of changes than they would be exposed to if they were to float down the stream with one particular body of water.

The sewage discharged from a city at night is a very different body, chemically, from that discharged by day. The sewage discharged during a heavy storm is very different from that discharged in dry weather. Again, the seasonal conditions must be taken into account, and in the case of the Illinois river physical conditions, such as floods in the tributaries, or the overflow of lakes upon these tributaries, bringing in new materials and a strange bacterial flora. These and many other things which I need not, and could not, mention undoubtedly play a highly important part. The trouble is that in trying to fix the longevity of typhoid fever or any other microbes we are dealing with extremely sensitive and almost infinitesimal organisms which we have only within the last few years learned to recognize at all, and have not yet by any means learned to know thoroughly. I believe, therefore, that while the experiments of the experts for the defense are interesting, in-
13137 genious and important in the science of bacteriology, they should not be allowed to have too much weight in determining the issues in this case.

MR. TODD: I move to strike out the last sentence in the witness's answer for the reason that it is not testimony, but argument.

MR. JEFFRIES: Q. Assuming, Professor, that the longevity of a typhoid fever germ in an open sewer, such as the drainage canal, as characterized by different witnesses, and as limited by the experiments of Doctors Zeit, Jordan and Russell to from two to four days, in what respect is the credibility of these experiments reflected upon by the ordinary, usual and general practice of sanitarians in the construction and recommendations for the construction of plants for the treatment of water for domestic purposes, which has been subjected to sewage pollution?

MR. TODD: Object to the question on the ground of its ambiguity, and it may be proper rebuttal and it may not.

A. As I understand the question, it is my opinion that their results are so far out of harmony with the results of previous investigators and so contrary to the prevailing opinion upon this subject which forms the basis of the practice
13138 of sanitarians and engineers in forming their opinions
concerning the availability of polluted streams for drinking and other domestic purposes, as to throw grave doubt upon the results, and therefore upon the conclusions to which these naturally lead.

MR. TODD: Move to strike out the answer for the reason it is argumentative and is not testimony.

Adjourned until 2:00 p. m., Friday, May 27, 1904.

13139 2:00 p. m., Friday, May 28, 1904.

Room 282 Southern Hotel, St. Louis, Mo.

Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. WILLIAM T. SEDGWICK

resumed the stand for further examination by Mr. Jeffries, and testified as follows:

Q. Professor, have you examined the testimony of Professor Mason with reference to the effect that increased typhoid fever in the city of Chicago would have upon typhoid conditions in the city of St. Louis, assuming that the germs of this disease pass from Chicago to St. Louis?

A. I have.

Q. State whether or not, based upon the chemical and bacterial analyses that have been introduced in evidence in this case on the part of the respondent, and upon the physical conditions and surroundings of the Illinois river, including the sanitary district of Chicago, what effect would you reasonably expect an increase in typhoid in Chicago to have upon typhoid conditions in St. Louis?

13140 MR. TODD: Object to the question for the reason that it is not proper rebuttal and was gone into in chief by this witness on his direct examination.

A. Taking into consideration the distance between the two cities and the time required for the passage of typhoid fever germs from Chicago to St. Louis down the drainage canal, the Desplaines, Illinois and Mississippi rivers, and taking into consideration also the character of the drainage canal and of the Illinois river, and considering also the fact that the water drawn from the intake at the chain of rocks by the city of St. Louis for its public supply is now, and long has been, subjected to extensive sedimentation, I should not expect to find any close correspondence between the details of the typhoid fever curves of the cities of Chicago and St. Louis over such periods.

We must also take into consideration the fact referred to by Professor Zeit in his testimony, that typhoid germs arriving at the city of St. Louis might act through the formation of local foci of infection, the time required for which must always be of uncertain duration.

I should therefore expect to find a correspondence between the prevalence of the diseases in the two cities, in general and broadly speaking, only when considerable periods were 13141 dealt with. It is of course probable that a very severe epidemic of typhoid fever in Chicago would make itself felt in St. Louis in such a way that cause and effect could be clearly connected, but here again much would depend upon the season of the year, the rate of flow in the Illinois and Mississippi rivers, the local conditions of the sewage, and the efficiency of sedimentation in the sedimentation basins of the water works of St. Louis. I am therefore not surprised to find that the curves of Professor Mason do not indicate any conspicuous and constant relation between waves of typhoid fever in Chicago and similar waves in St. Louis. I do believe, however, that by taking long periods and averages we ought to see and do see a definite connection, as for example when comparing typhoid fever in the years following 1900 with those preceding that date.

MR. JEFFRIES: Q. State whether or not you have examined the evidence of Professor Jordan and Professor Burrill upon the colon tests made by them and their evidence in connecion therewith?

A. I have.

Q. State, Professor, from the consideration of these colon tests and tables so introduced by Professors Jordan and Burrill, together with the other testimony upon the chemical and bacterial data, your conclusions as to the appearance of pathogenic bacteria in the waters of the Illinois river at its mouth, originating at Chicago? 13142

A. The tests applied by Professor Jordan and Professor Burrill to the waters of the Illinois river, while they show a very great decline in the numbers of these organisms present in the lower reaches of the river at the times when the specimens examined were taken, in those particular specimens, do not, in my opinion, enable any one to form an accurate opinion as to the presence or absence of typhoid fever germs in the waters of that river at those points.

The reasons for my opinion are, first, that only a comparatively small number of specimens was examined, and from the nature of the case such specimens only imperfectly represent the true and complete character of the stream at all times and all seasons, and, second, that while the colon test is a valuable aid in sanitary water analysis, it is by no means a sure and perfect measure of the presence or absence either of the bacillus coli itself or of the typhoid fever bacillus. It is not a sure and perfect test for the colon bacillus at all times because experiments have shown that this organism sometimes fails to make its appearance in the tests applied, even where it is proven to be present by a further study of the same specimen. 13143 And it is by no means a sure test of the presence or absence of the typhoid fever germ, not only for that reason, but also because it is not yet established beyond all reasonable doubt that the life of the typhoid fever germ so closely resembles that of the colon bacillus as to be fairly represented by it under all conditions at all times and all seasons.

I am therefore of the opinion that while the experiments of Professors Jordan and Burill throw great light upon the process of bacterial purification going on in the Illinois river, they do not by any means establish the fact that typhoid fever is completely or effectually removed from the waters of that river before it empties into the Mississippi at Grafton.

Q. State whether or not you have examined the tables and charts introduced in evidence by Mr. Lochridge, based upon the mortality record of typhoid, typho-malarial, intermittent, remittent, congestive and continued fevers and enteric and bilious fevers?

A. I have, and I am thoroughly familiar with them for the reason that Mr. Lochridge has frequently consulted me with reference to them, and their preparation, which was begun and carried out by him at my request and with my constant advice and supervision.

13144 Q. Will you examine those charts and tables and state what they show with reference to an increase or decrease in typhoid fever since January, 1900, to December, 1903, inclusive, as compared to a corresponding period immediately preceding, and taking into consideration in this connection the deaths reported from malaria, intermittent, remittent, typho-malarial, congestive and continued fevers?

MR. TODD: Object to the question for the same reasons advanced by me in my motion to exclude the testimony given by Mr. Lochridge in regard to these tables and for the additional reason that it is not rebuttal and is therefore incompetent, irrelevant and immaterial.

A. The typhoid fever deaths taken by themselves and alone, show a marked annual increase during the last four years, that is to say since the opening of the Chicago drainage canal. This increase, moreover, is not only considerable from year to year during this period but is much more marked than it was during the preceding period. In fact, during the four years, 1896 to 1899, inclusive, typhoid fever in the city of St. Louis may be said to have been stationary or very nearly so, and not at all excessive, the annual death rate from typhoid fever measured either by percentage mortality or by comparison with
13145 the total population having been such as, broadly speaking, prevails only in cities having good water supplies. But during the last four years of the period under consideration, typhoid fever in St. Louis has risen far above this level, until

it stands at the end of the period higher than at any time during the whole period under consideration.

The testimony introduced by the defendants having tended to show a possibility of the transfer of deaths from other diseases, especially remittent, intermittent, typho-malaria, congestive and simple continued fevers into the typhoid group, especially in the latter years under consideration, I have examined with special interest Mr. Lochridge's analysis of these several nondescript fevers, or rather of the deaths attributed to them, and tabulated by him upon his charts; for it was a possibility that some such transfer might in fact have been made. The unquestioned improvement in medical education which has been going on for the last twenty years, especially after the introduction of the Widal test, might conceivably have had some influence in causing such transfer, the effect of which would have been to increase the number of deaths attributed to typhoid fever in the latter years of the period under consideraton. Any such change must, however, of necessity, have been gradual, while in point of fact the increase of typhoid fever in the
13146 city of St. Louis was sudden, sharp and has thus far been continuous. In the second place the Widal test, having been introduced by the Board of Health of the city of St. Louis early in the year 1897 should have made its influence felt, if it had any in the direction indicated, previous to the year 1900, but no such influence is visible in the figures compiled by Mr. Lochridge or upon his charts. It is not, however, by any means clear that the Widal test woud always tend to increase the total deaths from typhoid fever for, while it unquestionably clears up the diagnosis, and in some cases perhaps leads to the recording of deaths as due to typhoid fever which without its use might have been referred to some other disease, the Widal test works also in the opposite direction, giving negative results in many suspected cases and removing from the typhoid group deaths which without its use might have appeared there. It is important to note that only from five to ten per cent. of the specimens sent in by physicians for the Widal test ordinarily prove positive and it is particularly important to note that in the city of St. Louis a large number of cases diagnosed as remittent fever, malaria and typho-malaria fever, the blood from

which was subjected to the Widal test, failed to give any typhoid reaction.

Again, Mr. Lochridge's compilations and charts throw 13147 great light upon the whole matter by enabling us to consider the ages of the decedents from the various diseases referred to, as well as the seasons in which they died; and a careful comparison of the incidence of death at the different ages and months, enables one to show beyond doubt that, even if a considerable proportion of the deaths from remittent, congestive and intermittent fevers which occurred previous to the year 1900 were by better diagnosis removed from those groups in the remaining years, these were not in point of fact transferred to the typhoid group.

As to the matter of season it is important to observe in the first place that Mr. Lochridge's charts indicate a considerable increase in typhoid fever in the city since January 1, 1900, at all seasons, but especially that this increase has been greater in the winter and the spring, than it has in the summer. This is one of the most important facts which I deduce from the charts, for it shows in the first place that the increased number of deaths found in the typhoid group is almost certainly, as proved by this test alone, not due to a transfer of malarial death to the typhoid column since malaria is not prevalent in the winter.

In the second place, this winter increase is extremely 13148 important for the reason that during the winter months the Missouri river is a less important factor in the water supply of St. Louis than it is during the summer months; so that this winter increase must have had its origin elsewhere than in the Missouri river. I do not think it necessary for me to dwell longer upon these charts which Mr. Lochridge has already explained in detail, and I believe that I have stated some of the principal conclusions to be drawn from them. I will, however, say before leaving them that they appear to me to prove beyond all reasonable doubt that the typhoid fever increase in the city of St. Louis since January 1, 1900, has not been due to any transfer of deaths from remittent, intermittent, congestive, typho-malaria, or simple continued fevers into the typhoid fever group.

One thing more I ought to mention. Mr. Lochridge has made a correction indicated by dotted lines upon some of the charts for the localized epidemic of typhoid fever which occurred

in November and December, 1899, and the deaths from which continued, apparently, into 1900. This epidemic, as I have taken pains to inform myself by inquiry of physicians in different parts of the city and otherwise, was localized in the west central portion of the city, was such that in
13149 my judgment could not have been due to a general pollution of the public water supply. I believe that it was due to milk, but I am unable to state this positively.

MR. TODD: I move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. In answer to your last question the last question of mine, did you take into consideration also the age of the patients dying?

MR. TODD: Object to the question for the reasons heretofore stated.

A. I believe that I briefly referred to that matter which is of special importance as establishing some of the facts and conclusions which I mentioned, in the deaths recorded as due to some of the fevers not typhoid. A comparison of the ages of decedents from these diseases and of those from typhoid fever makes it perfectly clear that if, as sometimes happens, the number of deaths from a disease in the first group has declined, this cannot be because deaths from this particular disease have been transferred to the typhoid fever group, for the reason that no deaths of corresponding ages can be found in that group.

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES: Q. State whether or not, Professor, from these charts and tables introduced in evidence by
13150 Mr. Lochridge, which are based upon the typhoid fever deaths and deaths from the nondescript fevers show in any way an increase of any character since the opening of the drainage canal which may be due to the influx of people on account of the construction of the Louisiana Purchase Exposition?

MR. TODD: Object to the question for the reasons heretofore stated.

A. Replying to this question I may say that I have given

in the past some attention to the influence which expositions of this kind have upon typhoid fever death rates, for the reason that in the year 1892 I studied the typhoid epidemic in Chicago, as I have already testified in this case. That date was just before the opening of the World's Columbian Exposition, and it was frequently alleged that the excess of typhoid fever in Chicago at that time was due to the influx of workmen and others preparing for that exposition. In studying this question I also examined the typhoid fever mortality of Philadelphia before, during and after the Centennial Exposition of 1876, and found that while typhoid fever was excessive in Philadelphia during the year of the exposition it was not much, if any, higher than usual during the years immediately preceding it. Further investigation led me to conclude that the excess of ty-
13151 phoid fever in Chicago just before the opening of that
exposition was not due to any influx of outsiders, but to a grossly contaminated water supply, and this latter opinion has come to be generally accepted as true. In fact, during the Exposition itself the typhoid fever in the city of Chicago was decidedly lower than it had been in the preceding year, owing to the energetic measures taken by the exposition and city authorities for improving the public water supply. In view of these facts I am of the opinion that no important portion of the increase in typhoid fever in the city of St. Louis since January 1, 1900, can reasonably be attributed to the influx of workmen or others connected with the World's Fair.

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

MR. JEFFRIES. Q. From the examination which you have made of the charts introduced by Mr. Lochridge, and from your general information upon the subject, epidemiologically and otherwise, state what effect in your opinion circular letters sent out by the health department from year to year has had upon the mortality records of the city of St. Louis and especially with reference to typhoid conditions?

MR. TODD: Object to the question for the reasons
13152 heretofore stated.

A. I have had much experience with boards of health and their workings, and in many cities I have had occasion to observe that circulars of this kind, issued by boards of health are generally ignored altogether. I am of the opinion that no circulars issued by any board of health and urging the reporting of *cases* of typhoid fever could have any influence upon the reporting of *deaths* from that disease, for the reason that physicians are legally bound to report deaths anyhow, before a burial permit can be obtained from the board of health or other municipal authority. Such circulars in fact sometimes tend to diminish the number of deaths reported from typhoid fever rather than to increase them. I have, indeed, known of a few instances in which a physician had reported a death really due to typhoid fever as due to some other disease because, having failed to report it while living as a case of infectious disease, as required, he feared to incur the displeasure of the authorities if he should report it as a death from that disease and thus possibly subject himself to a summons, a fine, or other penalty.

MR. TODD: Move to strike out the answer for the reasons stated in my objection to the question.

13153 MR. JEFFRIES: Q. Professor, Dr. Zeit in his testimony along with other witnesses for the defendant attributed extensive destructive effects upon typhoid fever germs in sewage and sewage polluted water to the toxic products of the saprophytes in sewage. State whether or not bacteriologists and epidemiologists agree with him as to these facts?

MR. TODD: Objected to for the reason that the evidence in this case, if read by the Court, will show that bacteriologists and epidemiologists do not agree upon that one point and this witness is already on record as opposed to the theory of Professor Zeit, and Professors Jordan and Russell and the other witnesses who have testified on that subject.

A. Unquestionably some would agree with him. Others, like, myself, do not accept this view and against Dr. Zeit's theory I may quote the following experiment made by myself and one of my students, Mr. D. D. Jackson, as long ago as 1893. In this experiment we undertook to test the very point under consideration. A portion of sewage was carefully freed, by filtration, from all microbes present, whether saprophytic or parasitic. The filtrate was proved to be free from such germs, but was otherwise ordinary sewage, that is to say it contained the toxic products, if any, of the saprophytes which it con-

13154 tained in abundance and which had been removed by filtration. A portion of this filtered sewage was then seeded with typhoid fever microbes, to the number of 329 per cc. Now if the toxic products of saprophytes had been capable of destroying typhoid fever germs these should have gradually declined in number. The facts were, however, that one hour later the number present was 333 per cc.; 24 hours later, 63,198, and two days later the typhoid fever germs present were innumerable. This specimen was kept at blood heat. The germs were carefully examined to make certain that they were true typhoid fever bacilli and were found to be such. The culture was next placed in the ice chest and six days later the number of typhoid fever germs present had fallen to 888,000 per cc.; 12 days after seeding the number present was 832,100 per cc.; 20 days after seeding the number present was 375,000 and 36 days afterwards 56,500. This experiment satisfied me that whether or not typhoid fever germs ultimately disappear in sewage they are not readily destroyed by the toxic products of saprophytes, but rather multiply and live long in their presence.

More recently a similar experiment has been made by Dr. W. H. Horrocks, a well known English bacteriologist in which Dr. Horrocks found abundant typhoid fever germs in sewage, filtered in the same way, after 42 days.

MR. JEFFRIES: Q. Professor, you have examined the 13155 tables introduced in evidence in this case, contained in the book known as Streams Examination?

A. I have.

Q. You have examined the tables and charts contained in the Illinois State Board of Health Report introduced in evidence by Professor Long?

A. I have.

Q. State whether or not you have examined the tables introduced in evidence by Professor Palmer aside from those made up by him and contained in Streams Examination?

A. Yes, sir, I have.

Q. Have you examined the tables and bacterial and chemical data of Professors Jordan and Zeit upon the various chemical and bacterial determinations of the water in the Illinois river and the sanitary canal not contained in Streams examination?

A. I have; yes, sir.

Q. Taking into consideration, Professor, all of the chemical and bacterial data introduced in evidence by the respondents, state whether or not the data so introduced leads you in any way to change your former opinion expressed in this case?

A. I have obtained from these tables and other data a 13156 much better knowledge of the process of chemical and bacterial purification going on at certain times and seasons in the Illinois river, but I have failed to discover any reason for changing the opinion which I expressed on my examination in chief a year ago, namely, that the principal part of the increase of typhoid fever in the city of St. Louis since the first of January, 1900, has been due to the presence of deleterious elements contained in the public water supply, and derived from the unpurified sewage of the city of Chicago. The additional information which I have gained on the history of typhoid fever and other fevers in St. Louis, especially during the last year, has only served to strengthen that opinion.

CROSS-EXAMINATION, by Mr. Todd.

Q. Professor, in the experiment which you made and introduced in evidence upon the longevity of the typhoid in the effluent of filtered sewage, what was the character of the sewage employed in the making of that experiment?

A. Owing to the fact that this experiment was made more than ten years ago, I am unable to state the precise source from which the sewage was derived, but I have reason to think that it was from the sewers of the city of Lawrence, inasmuch 13157 as at that time I was frequently visiting Lawrence and officially connected with the Sewage Experiment Station of the State Board of Health of Massachusetts located there.

Q. Have you done any work in bacteriology yourself in recent years?

A. If you mean personal work in the laboratory with the bacteria themselves, I shall have to answer, not much, although I am constantly in touch with the subject, partly by teaching some portions of it, and partly through my several assistants, and graduate and special students, all of whom are actively engaged in personal work on the subject.

Q. In your line of work does it have to do with original research in bacteriology?

A. Yes, sir, my professional work brings me constantly in touch with original work in bacteriology. For example, I am at this moment director of a new Sanitary Research Laboratory and Sewerage Experiment Station recently established by the Massachusetts Institute of Technology. In my official capacity as director I have there constantly to consider problems of original work in bacteriology and sanitary chemistry, and I have also constantly, either immediately under my own supervision, or in my laboratory under my frequent observation, young
13158 men and young women working at original problems in bacteriology, sanitary science and public health.

WILLIAM T. SEDGWICK.

MR. JEFFRIES: I REST.

THE COMMISSIONER: Complainant's case in rebuttal is here closed.

MR. TODD: I offer in evidence, on behalf of the respondents, in sur rebuttal, the annual reports of the Health Commissioner of the city of St. Louis, published by the Board of Health of the city of St. Louis for the years from 1890 to 1903, inclusive, and ask to have them marked respondents' sur-rebuttal exhibit "A." (See Note next page.)

Mr. Jeffries: Objected to for the reason stated at the time of the introduction of the evidence of the witness E. E. Lochridge, on the part of the complainant, in rebuttal, wherein the evidence upon the facts contained in the original health records in the mortuary office of the health department of the city of St. Louis was introduced with reference to the inter-
13159 mittent, remittent, malaria and malarial fevers, typho-malaria, congestive, continued fevers, bowel and enteric fevers and typhoid fevers, and for the further reason that said reports are not shown to contain accurate calculations or tabulations of the number of deaths occurring for the respective years, and for the further reason that said report does not contain the full information required by competent witnesses for respondent, wherein those reports are criticized.

And I object to the introduction of the reports for the further reason that their correctness and accuracy and credibility have been attacked and shown to exist in part by the statements of witnesses for the respondents and I object to their introduction for the further reason that expert witnesses for the defendants stated while upon the witness stand that epidemiologists were unable as a rule to obtain accurate and correct data with reference to the number of deaths occurring in the great municipalities of this country because of the inaccurate manner in which the tabulations in public health reports are made up and published.

I object to the introduction of the reports in question for 13160 the reason that they are incompetent, irrelevant and immaterial and not competent proof.

Mr. Todd: In reply will state that in view of the misunderstanding existing between counsel for complainant and the defendants in regard to an agreement wherein these reports were to be placed in evidence, which agreement was made when Dr. Teichmann was on the stand, as the evidence of Dr. Teichmann, wherein he identified certain board of health reports that were offered, I have offered the entire reports covering the period of these investigations, and submit that these are admissible in evidence as being the official reports of the health department of the city of St. Louis.

Which said reports are considered offered in evidence.

Mr. Todd: In behalf of the State of Illinois and the Sanitary District of Chicago, defendants in this case, I rest the case in behalf of the defendants.

The Commissioner: Gentlemen, my commission for taking the testimony in this case is now closed and further hearing is adjourned without day.

Note.—Defendants have furnished the Commissioner only the following annual reports of the Health Commissioner of St. Louis (being each for the year ending March 31), 1892, 1894, 1895, 1896, 1897, 1901, 1902; and in lieu of the annual reports the monthly bulletins of the Health Commissioner of St. Louis for 1897-8 and 1902-3, all of which have been marked by the Commissioner "Respondent's Sur-Rebuttal Exhibits 'A.'"

Complainant assents.

72

IN THE

Supreme Court

OF THE UNITED STATES

October Term, A. D. 1905

THE STATE OF MISSOURI,
vs.
THE STATE OF ILLINOIS
AND SANITARY DISTRICT
OF CHICAGO.

Abstract of Record for Defendants

W. H. STEAD,
Attorney General of Illinois,
H. J. HAMLIN,
of Counsel.

JAMES TODD,
Attorney Sanitary District of Chicago.
JOHN G. DRENNAN,
of Counsel.

IN THE

Supreme Court of the United States.

October Term, A. D. 1905.

THE STATE OF MISSOURI
vs.
THE STATE OF ILLINOIS AND THE SANITARY DISTRICT OF CHICAGO.

Abstract of Record.

Before
FRANK S. BRIGHT,
Commissioner of the Supreme Court of the United States.

1 Testimony begun at City Hall, St. Louis, Mo., Feb. 17, 1903, at 10 A. M., pursuant to order heretofore entered in said cause.

Present:

The Commissioner;

Attorney General Edward C. Crow, Charles W. Bates, and S. B. Jeffries,
On behalf of Missouri.

Attorney General H. J. Hamlin,
On behalf of Illinois.

William M. Springer, and
J. G. Drennan,
On behalf of Sanitary District of Chicago.

2 THE COMMISSIONER: My commission is now open and I am ready to hear testimony pursuant to rule heretofore entered by the Supreme Court and notice of Complainant's Solicitors.

Adjournment.

Met pursuant to adjournment at same place at 2 P. M., same day.

Present, same parties and Alexander Nicholson, also representing complainant.

AMAND NICHOLAS RAVOLD, called in behalf of complainant, after being duly sworn by the Commissioner, on direct examination by Attorney General Crow, testified as follows:

Reside at 2806 Morgan st,. St. Louis, Mo. Am a physician and have been practicing since 1881. Since 1885 have been a professional bacteriologist. Was first connected with Shaw School of Botany in 1886—was assistant to Prof. William Trelease at Washington University. In 1887 became lecturer on bacteriology in medical department of Washington University. Then known as St. Louis Medical College. Later was professor of Bacteriology in medical department of Washington University and continued so until last year when I resigned to go abroad.

3 The Washington University Medical College stands now with reference to other schools as one of the great schools of the country.

6 A non-pathogenic organism is one that does no harm to an animal, while a pathogenic organism is one that lives in his tissue and does him harm.

In 1894 I was employed by the St. Louis health department—the city government—to aid in the bacteriological work of the health department. My title was consulting bacteriologist. I then made bacterial culture experiments and did any work of that kind that came in; I carried out experiments for the department working on tuberculosis, diphtheria, typhoid, blood and various things that came up at that time, and made diphtheria anti-toxin.

7 Bacteriology in the medical world means the study of bacteria. Bacteria are the lowest forms of vegetable life. They are closely allied to the algae. They belong to the group thallophyta, and come in the division known as schizomycetes or fission fungi. They are found everywhere on earth, on the surface of the earth, more or less on the surface or in the earth in the waters of the earth and in the air close to it, even extending up to some height, as high as they can go, as high as the currents of the air will carry them above the earth's surface.

(Gives a history of the origin and development of the science of bacteriology.)

10 Pure culture means that a micro-organism, say anthrax bacilli, are separated out and made to grow alone in the medium or upon the medium. It is free of every other micro-organism, it is a pure culture and if it is not free of every other micro-organism, it is impure culture.

11 Prior to along about 1849 or 1850 there had been no demonstration in the scientific world that showed that bacilli had any particular relation to diseases of the human body.

17 Explains the manufacture of anti-toxin for diphtheria.

22 Some bacteria are water born and others are not. Most of the bacteria can be water born for a short distance, but many of them die—very many—in water. The water born diseases as we know them are typhoid fever, the cholera and dysentery. Most of the other bacteria are in the soil or in the air.

There would be no life on earth without bacteria, consequently they are the undertakers of the organic world. By this I mean that when an animal dies or a tree falls, in a short while, as we know, that material begins to break down. After it lies awhile we see that it gradually disappears, breaks apart and finally disappears, and so with an animal dead upon the field. It swells up and stinks for a while and then disappears, leaving

nothing but bones. Now the cause of the disappearance of a tree or the meat of a dog or dead animal are the result of a destructive action of the bacteria upon the chemical compounds that compose the heterogeneous structure of that animal. They reduce, in other words, the highly complex nitrogeneous compounds and carbon compounds to the lower forms of carbon,
hydrogen, oxygen and nitrogen.
23 These are the four basic forms of animal and vegetable
life. These heterogeneous molecules are broken up so that in the end we have ammonia and carbon dioxide as a result. The carbon dioxide passes off in the air. Ultimately these complex heterogeneous structures are reduced to the elements from which they came. These simple compounds form the food for plants again, and the plants take up this broken material, and grow. Plants are food for animals, hence animals upon earth; so that without bacteria there would be no life upon
earth. They are also the destroyers of the organic world.
24 Bacteria destroy sewage, for instance. That is, sewage
in a tank is destroyed by them.

Q. Now what is it the septic tank produces?

A. It consists in running crude sewage into tanks hermetically sealed, and the bacteria there being of two kinds, aerobic and anaerobic, break up the organic compounds of the sewage. I am using crude sewage in the technical sense. It doesn't make any difference whether it is diluted or concentrated sewage. It is run into these practically hermetically sealed tanks. The aerobic micro-organisms act upon the sewage, first working in the presence of the oxygen of the air in the sewage; so soon as the available oxygen is used up, the aerobic bacteria cease their destructive action on the sewage which gives the anaerobic bacteria which flourish best in the absence of oxygen a chance to attack the organic compounds of the sewage. The result of the destructive action of these two kinds of bacteria on the sewage is to quickly liquify the solid organic ma-
terials and to reduce them to lower and lower nitrogen-
25 eous and carbonaceous compounds. Ultimately am-

monia, carbon dioxide, hydrogen and marsh gas are produced, which are gases and lower forms of nitrogen and carbon compounds which are food for plants.

I have one of these tanks in my cottage in the north. It works during the whole summer, and it works in the way I spoke of it.

Those bacteria are present in all sewage mostly.

An enormous number of bacteria in the world are beneficial, and a great many of them are harmless. There is only an occasional one that is harmful.

The bacteria that has been looked upon as the index of fecal pollution and is found in water fed by sewage, and in the stomach of animals, including man—or rather in the intestinal canal is called bacillus coli communis.

26 By fecal pollution I mean that whenever there is sewage from man or animals the bacillus coli communis is generally found present.

They are also found in discharges from man or animals on the soil or anywhere else. In some of our work we found that it does not exist in the intestinal canal of fish in the ordinary streams, but in the fish of the Illinois river it exists in very large numbers in the intestinal canal—in about 70 per cent of the fish. In the fish in ordinary streams it does not exist, but in the highly polluted water of the Illinois river we found the bacillus coli communis in the intestinal contents of the fish taken from that river.

29 Koch discovered the cholera bacteria in the intestinal contents of people sick or dead of the disease, and he found it in the water of one of the tanks in India, from which the cholera had come, from which an epidemic of cholera had spread. He put it in steriled water and also studied it in living water, and he found that it would live a definite number of days in various kinds of water. It is subject to changes of temperature—water hot and cold. It takes a temperature of boiling water to kill it. Boiling water is 100 degrees centigrade. It takes five or ten minutes. It will stand indefinite freezing—

that is steady cold; but alternate heat and freezing will destroy great numbers of the bacteria very rapidly. It is highly active —it is motile, a swimmer.

30 It increases very rapidly. Increases most rapidly in the human system. I think no experiments have shown that it multiples in the water. It will grow on all media easily? It is a water born disease. There is a possibility of taking it through the air.

31 All bacteria arrest their own destructiveness—both the injurious and non-injurious. Bacteria growing on or in a medium produce toxins and after a time when they accumulate in sufficient quantities, stop the growth of the bacteria. They do not destroy exactly, but there is not enough nutritive media left for them to grow upon, besides the toxin produced inhibit the growth of the micro-organism. A man might have diphtheria or typhoid fever, and not be free of poison, and still recover.

32 The body itself produces anti-toxin to the specific bacteria.

Q. Well, does the poison that is thrown off with this bacteria, so that a man gets well without the pure anti-toxin, does that have the effect of curing him of his disease?

A. Yes, sir. A spore is known as the resting stage of the micro-organism.

(Describes spores and bacteria and method of propagation.)

33 A spore is the most high vitalized thing on earth. Some of the pathogenic organisms form spores, the anthrax bacillus for instance. That is a highly resisting spore. Tetanus (lock jaw) has a highly resisting spore that is especially obnoxious.

Typhoid fever, cholera or diphtheria have no spores. Tetanus and anthrax are the principal bacteria having spores.

(Explains method of sand filteration in which bacteria form part of the system.)

36 These filters have proved efficient and perfect. Typhoid

bacilli will occasionally go through this. That is demonstrated by typhoid fever breaking out in a community where these filters exist.

37 A good filter, kept in proper shape at all times will stop typhoid. It will work if the individual who is using it is a skilled man and will take care of himself, but if it is left to the ordinary servant it will be in bad condition at all times.

38 Bacteria are classed into the pathogenic or non-pathogenic; those that produce disease and those that do not produce disease. The non-pathogenic are the most prevalent. A general classification shows the non-pathogenic exists in vastly great numbers.

39 The aerobic bacteria is the most active agency in the destruction of sewage in the open stream. The effect of that upon the sewage in the running water would be its gradual reduction from the higher compounds to the lower compounds.

Q. Now would that reduction affect the vitality or existence of the disease bearing bacteria in that running water?

A. Not the mere destruction of the bacteria in the water, no, but the action of the toxins of the individual bacteria upon one another is a vital problem. By that I mean this: You take bacteria confined in a space all growing vigorously and active, and each producing its kinds, and giving forth its products, these products are not only poisonous to themselves, but poisonous to other bacteria around them, and some bacteria produce poisons that are very deleterious to others. That is true of the bacteria in running water.

Q. Is it known that the injurious agencies are running and operating in the running water, and whether in that way they tend to destroy the cholera or typhoid or dysentery bacteria?

A. Now if the waters available were merely polluted, the action would be much less where the water was confined than where it was running.

Q. In this form of water there would be less liability of the destruction of these bacteria than there would be if they were confined and the water was still?

A. Yes, they would die much quicker in stagnant water than in running water.

Q. In other words, the toxin would be much freer to have its effect?

A. Yes, sir.

41 This process (septic tank) tends to destroy typhoid and cholera germs. Also dysentery germs.

A septic tank properly constructed and maintained in a proper way would be an absolutely sure day of destroying any germ bearing bacteria in the sewage of a city, if the sewage of a city was confined exclusively in septic tanks.

There are several cities in England that have these tanks. They are experimenting with septic tanks in Massachusetts. I do not know just now of any place where they have got beyond the experimental stage.

43 Inspected the sewage system of Berlin. They have the sewage farm system. The sewage is collected in large reservoirs in the town and from these reservoirs it is pumped out on to what used to be a sandy waste. The water is pumped up into the tanks upon those places, and then distributed for irrigation all over those farms, and it lies upon the surface for a time, percolates down through the sand, and a good deal of it passes into large ditches at the side of the field and out into the water courses. The bacteria are eliminated on the fields—the sand fields, by the filtration. At top of the soil they are held and destroyed. It is a fine way to conduct a city sewage system.

44 The pollution of sewage in running water must be very great in order to cause experts to say that the water is no longer healthful to use for domestic purposes. The volume of water does not destroy the bacteria.

45 My experience would be, and I believe the fact to be that the disease bearing germs that flow away from a city in

the sewage of that city would be borne mostly from the homes of the city where the disease existed.

46 Epidemics of typhoid and cholera and dysentery are usually caused, or believed at least to be caused, by the water born micro-organisms, which means a tainted water supply. That is true in this country at this date. The most common disease bearing bacteria that is born in the water of this country is typhoid. The reason for this is because crude sewage is discharged into the water closets, and water closets discharge into sources of water supply. Crude sewage is sewage that is not treated—disinfected.

47 Cholera germs live in the Mississippi river here, in the sunlight and dark, from 12 to 25 days.

If the Mississippi river had cholera germs in it and it should freeze over, it would not hurt them. It would not hurt typhoid fever germs.

In 1892 an epidemic of cholera was caused at Hamburg, Germany, from the dejecta of Jews suffering with the disease which was thrown in the River Elbe, that river being used as a source of water supply for Hamburg.

49 My experiments lead me to believe that typhoid bacteria will live in Mississippi river water here at St. Louis in the sunlight as high as eight days and in the dark as high as 21. That is living water.

50 The scientists of the Massachusetts state board of health found that they (typhoid bacteria) would live 25 days in the water of the Merrimac, in experiments at Lawrence and Lowell.

Q. Is there any other place where they have ever experimented?

A. Yes, throughout the literature, quite a number.

Q. What would be the average time?

A. About that time—from a few days to as high as 25 and 30 days, and always longer in steriled water, of course.

The effect of the sand filters at the places where I observed them, in London and other places, was to diminish the amount of typhoid and other diseases from the water-born bacteria.

Have had no experience with any typhoid epidemic in this country other than in the city of St. Louis. That was in 1892 prior to the time that the present intake was placed at its present existing spot. The intake was then at Bissell's Point. The present intake I suppose is six or eight miles above that on the river. Both on the Mississippi river. I do not know the width of the river at the present place of the intake. It is fourteen miles above the city, I think. Six or eight miles below the confluence of the Missouri and the Mississippi rivers. The division of the waters at the confluence of the two streams is quite perceptible. At the intake if the Missouri river is very high it can be very distinctly seen at the intake. Its great volume of
53 yellow water runs down clinging to the Missouri shore,
and can be seen. If the Mississippi is high and the Missouri not high, the effect of its waters can be seen at the intake.

Q. Well, if the Mississippi is very high and the Illinois is very high and the Missouri is not, what effect has that on the volume or character of the volume of water that comes over to the intake and into the waterworks?

A. Well, as a rule under those conditions the Missouri predominates.

Q. Where the Mississippi is high?

A. Not where the Mississippi is high.

Q. I mean where the Mississippi is high and the other two are low, in ordinary stages?

A. Then the waters exist in about equal quantities, or the Mississippi water may predominate. It appears that way to the naked eye.

Q. Now you stated that the bacteria in the water at the intake tower, when you cross sectioned the river there, would indicate the presence of more than one stream?

A. Yes, sir.

Q. What is there in the indication of that bacteria that indicates that to a scientific investigator?

A. Well, we know the numbers of bacteria in the Missouri river before it enters the Mississippi; we know the numbers of bacteria in the Mississippi above the junction with the Missouri river, and that these two streams flow down together, the Missouri clinging to the Missouri shore, the Illinois and Mississippi rivers combined, clinging to the Illinois shore, now the cross section of the stream will show whether the greater number of bacteria are on the Missouri side or on the Illinois side; then we can finally reach the point where we can see the two streams are about to touch one another, or commingle.

Q. Now you use the term "bacteria" without regard to whether they are injurious or non-injurious?

A. They are non-injurious.

Q. That is, they are simply indigenous to running water?

A. Water born. They are found everywhere in the
54 water of these two streams. They are the same bacteria.

Q. Is there anything to indicate after the Illinois enters the Mississippi below the mouth, the presence of the Illinois river, in the Mississippi river water?

A. No, sir. The bacteria of the Illinois are very similar in numbers and character to those in the Mississippi, and it is only by putting different kind of bacteria in the Illinois river and watching them as they flow, that we can trace the Illinois river water, species of bacteria that are not indigenous to either stream.

As to the waters, a visual inspection will show that samples from the Illinois and Mississippi are of a less muddy color, and contain less sediment than the samples from the Missouri in the greater part of the year.

55 My impression was that the Mississippi above the Illinois is more rapid than the Missouri above the Illinois. That is in equal stages of water. The more rapid the stream the further the bacteria carry. I think the Missouri would sediment its bacteria much quicker, because the sediment in the stream is very much larger. All inorganic particles are larger

and would carry down the bacteria in the water very much more rapidly than the Mississippi river will.

Q. What would be the result of that on the number of bacteria the non-injurious bacteria, that are just useful water-born bacteria, in the two streams, in the same volume of water? Both running at about equal speed?

A. For some reason or other the Missouri has the larger number.

Q. Now they are non-pathogenic, are they?

A. Yes, sir, a great majority of them.

56 The sand in the soil above the mouth of the Missouri river, contains large numbers of bacteria. I am speaking of the Missouri. They were alive.

Q. Now, are they non-pathogenic?

A. A great majority of them.

Q. Harmless?

A. Yes, sir.

Have examined at the confluence of the two rivers, the soil and the sand in the bottom of the Mississippi. Found a large number of bacteria, a very large number.

Q. What was the character of these bacteria?

A. Mostly harmless.

Q. Now do you know anything about the proportion of the bacteria in the two rivers and the sand and soil on the bottom of the two rivers at the point I mention, the confluence, as to which has the greater number of bacteria?

A. Practically about the same.

Q. Could you distinguish between the pathogenic and non-pathogenic bacteria?

A. What do you mean?

Q. Why in counting these bacteria that you discovered in your examination, in your estimate of the two rivers, or in the waters of the two rivers?

A. Not without separating out each individual bacterium to get it as a pure culture.

Q. Have you done that?

A. I have separated out different varieties or different species found in the rivers, the Missouri, the Mississippi, and the Illinois, at Peoria and Grafton.

Q. Well, by this method of separation then, the numbers of pathogenic and non-pathogenic bacteria could absolutely be determined?

A. Yes, sir, but not absolutely. It would be a slow process, a gigantic task.

Adjourned.

Met pursuant to adjournment at Southern Hotel, at 10:00 A. M., February 18, 1903.

Present, the Commissioner and same counsel.

I am familiar with what is known as the Chicago Drainage Canal.

59 I know that Lockport and Joliet and Peoria—most of the towns along the (Illinois) river that have a sewage supply whatever, discharge the sewage into the river.

65 I am familiar with the St. Louis intake—that is the place where the water supply for St. Louis is taken.

66 In the Mississippi river, on the Missouri side of the Mississippi river, 1500 feet from the shore is built a large tower of stone. Connecting with that tower there is a tunnel in the bed of the river to the shore. It runs alongside of what is known as the Chain of Rocks, which were put out there to deflect the flow of the river away from the Missouri shore. The water passes down through openings in this tower into the tunnel; from the tunnel it runs into what is known as the uptake and reservoir and from there to the pumps or to the reservoirs, six in number. After settling in these reservoirs the water is allowed to rest in these reservoirs from 24 to 48 hours, generally 36 hours. It passes out into a conduit and is carried to St. Louis. On the way it meets the pumps at Baden. The high service pumps there pump the water into what is known as the high surface tower which is located on Grand and La Fayette avenues. From there it is distributed throughout the west-

ern part of the city, and the high portions of the central portions of the city. The remaining part of the water passes on to Bissel Point, and there passes into reservoirs, and rests for a time in the reservoirs, to pass from the reservoirs into a series of low service pumps which supply all this part of the city, the low part of the city, the central part of the city.

67 I think it is six miles from the settling basins to Baden and eight miles to the low service pumps or low service reservoir at Bissell Point. From Baden to the high service reservoir I suppose it is 3 or 4 miles. The distance from Baden to where the low service basins are located is two miles. The tunnel that runs from the tower in the river to the shore I think is an eight foot tunnel. That tunnel is walled with stone and brick.

68 The settling basins are very large. The tower in the river is in the main channel of the Mississippi river. I do not know exactly the width of the river at that point. In the ordinary stages of the river I would say it was a mile across.

It is eight miles from the water tower in the river to the point of conjunction of the Mississippi and the Missouri rivers. It is 25 miles to the conjunction of the Illinois and the Mississippi.

At the intake of the St. Louis Water Works there are no filtration plants or processes anywhere that the water passes through or over between the time that it enters the tower in the river up to the time that it goes out in the service pipes. The subsidence that occurs while the water is resting in the reservoirs at the Chain of Rocks is the only treatment whatever that the water receives.

All fecal matter of a man or animal contains what is known as bacillus coli communis.

Fecal matter is the intestinal contents discharged from man, from the bowels of man and animal.

This bacillus coli communis is found in animals and also in fish.

I have been unable to find any reference whatever that shows that it has been found in fish prior to my investigation.

We found the bacillus coli communis in the waters of the drainage canal, the Des Plaines river, the Illinois and Mississippi.

69 The finding of bacilli coli communis is looked upon by bacteriologists as the index to fecal pollution, for the reason that whenever these micro-organisms have been found in water, the conclusion is reached that the water must contain sewage, either from the intestinal contents of man or animals. It is an indication of sewage in water.

There are several other bacilli that are found in running streams that are an indication also of sewage in water. But there really is no good index. There are micro-organisms that are found in sewage steadily wherever sewage is present, but a true index to fecal pollution, I don't know a single one.

Q. Now do you mean to include in that statement the bacilli that we have been talking about?

A. Yes, sir, that is, previous to our work upon the intestinal contents of fishes, these micro-organisms were really looked upon, and I believe it is still by Prof. Jordan, looked upon as an index to fecal pollution, but our own experi-
70 ence robbed it of that dignity.

The reason for this is that if it is found in a stream steadily, and we know that fish in the stream at the same time, not only have had in their intestinal contents and have it in there, and are discharging it from their intestines, then the bacilli coli communis found in that particular water may be either from sewage, from man, or from animals, or fish.

We have found it in fish in the Illinois river. Also in carp in the Mississippi. Am not sure whether I found it in the fish of the Missouri river—I think not.

Whatever fish we found in the canal, the drainage canal, were dead. We didn't go into their intestinal contents at all. They were killed by the fact that the aerobic micro-organisms which are present in water polluted by sewage, consumed

71 the oxygen that was in the air in the water. That leaves the water without air for the fish to breathe, and having no air to breathe, they die.

The cause of the presence of large numbers of these aerobic micro-organisms was due to the fact of sewage in the water.

Don't know whether there are any fish in the Des Plaines river. Saw men fishing there. Examined 68 fish in the course of several months in 1900—1899 and 1900.

Was consulting bacteriologist for St. Louis in July, 1899. Health Commissioner was ordered by a motion made in the city council, to have investigations made, and I was assigned to the work.

72 Suit was begun 22d of January, 1900. Had made investigation of the waters of the Mississippi and Illinois between that date and July, 1899, and the drainage canal. *Began work August 10, 1899.* Consisted in taking samples from the water at various points, in four ounce bottles.

73 The examination made was of a bacteriological nature. The water was taken with a special apparatus designed by me, in sterile vessels, from about 3 feet below the sur-

74 face of the river.

Sterilizing may be done by three methods. (Methods explained.)

75 Constructed special apparatus for taking samples.

76 There are particular rules or methods adopted generally by bacteriologists in this country, in the examination of water and other things for the discovery of bacteria.

The American Public Health Association—the bacteriological committee, have published a report in 1898 and is called "Procedures recommended for the study of bacteria, with special reference to a greater uniformity in the description and differentiation of species. Being a report of a committee of the American Bacteriologists to the committee on pollution of water supplies of the American Public Health Association, submitted at the meeting of the Association in Philadelphia, September, 1897, published by the Rumford Press. 1898."

This report made part of the record that outlines the method that is approved by bacteriologists generally.

At a meeting in 1901, a few minutes were made in some of the details or media.

77 We collected samples at the intake of the St. Louis water works. We immediately plated them.

We followed the method laid down in that volume for the preparation of media throughout, by plating I mean we mixed a definite quantity of the water from the sample with the media in a tube and poured it out in a petri dish. This was put in the ice chest, kept at a temperature of 20 centigrade about 60 Fahrenheit, and the bacteria allowed to grow for two or three days, and the colonies of bacteria which have formed are counted. Each colony is considered one bacterium. The number is then recorded. Now for each sample of water we made from two to three plates. The result of these investigations simply gives the unclassified number of bacteria.

Besides that we carried out some work identifying the number of bacilli coli communis in sterilized water collected at these points.

These collections were made at the Mississippi river just above the intake of the St. Louis water works, August 10,
79 and Aug. 30, 1899. Two plates were used of each sample.

The results shown are the mean number of bacilli on the two plates at each point, per cubic centimeter of all kinds.

80 Mississippi river just above the intake,

August 10, 275 bacteria,
August 30, 275 bacteria,
September 12, 650 bacteria,
September 13, 1500 bacteria,
September 15, 2300 bacteria,
September 16, 1700 bacteria,
September 20, 1200 bacteria,
September 25, 3600 bacteria,

Illinois side of the intake, toward the Illinois shore directly in line with the intake, on August 23d, the number of bacteria was 240.

In the intake, as the water flowed into the intake,
August 10, 500 bacteria,
August 21, 375 bacteria,
August 22, 950 bacteria,
August 23, 550 bacteria.

After this water had flown from the river and discharged into the uptake, a sample of water was taken from the uptake. From the tower to the shore is a tunnel, and when it flowed out of the end of the tunnel, 1500 feet from the river, a sample was taken there. As I say, we found no difference in the numbers in the intake and the uptake, as you see:

(Following is all uptake)
August 10, 600,
August 11, 650,
August 12, 650,
August 14, 650,
August 15, 1500,
81 August 17, 750,
August 18, 650,
August 19, 400,
August 21, 325,
August 22, 150,
August 23, 1300,
August 24, 475,
August 25, 400,
August 26, 275,
August 28, 275,
August 29, 170,
August 30, 300,
September 4, 300,
September 5, 270,
September 11, 300,

Made six boat trips up the river between August and January 23d. Up the Mississippi to the mouth of the Missouri.

In the Illinois as far as the brick house club, 5 or 6 miles up the river and 2 or 3 or 4 miles up the Mississippi above the conjunction with the Illinois river, and samples were collected at different points between those.

82 We took 32 samples. Colon basillus in the presence of sugar produces fermentation, it breaks up the sugar, producing gases. Now if we can put sugar broth into a U tube known as a fermentation tube, and have the glass arm filled with broth and the open arm so that we can throw water into it, if the bacillus coli communis is there, it will break up that sugar and form gases in the glass tube. The gases form at the top and force the water down. It produces as a rule about 60% of gas in the tube, so when we put a small quantity of water in the fermentation tube and collect about 40 to 60% gas, sometimes 75%, we know there is gas-producing bacillus there, and then we merely search for this gas producer by plating and studying the colony characteristics of the micro-organism that we think produce this gas. The micro-organism is picked off and showed on a variety of media, its microscopic form and motility studied.

Motility means whether it swims in fluid or not.

This is not the character of coli work that was carried on on these boat trips, altogether. Samples were returned to my laboratory in the city chemist's office, and there these experiments were carried out.

Result of examinations, number of unclassified bacteria, is as follows:

83 September 6, Illinois river, Wheeler's ferry, 3 miles above the mouth, 130 bacteria.

Illinois river, five miles above the mouth, at Grafton, what is known as Brick House club, 170 bacteria.

Illinois river, 7 miles above Grafton, 6 mile Island, 160 bacteria.

Following is Mississippi river:
September 6—all on same day.
Opposite Grafton, 190 bacteria;
4 miles above Grafton, 550 bacteria;
6 miles above Grafton, 276 bacteria.
Above plated on harbor boat after collection.
September 9th:
Mississippi river as follows:
Chain of Rocks, 160 bacteria;
Madison Landing, above mouth of Missouri, 210 bacteria;
1½ miles below Alton, in the channel, 190 bacteria;
1 mile above Alton, 240 bacteria;
1 mile below Grafton, 160 bacteria;
Opposite Grafton, 150 bacteria;
Missouri river, near mouth, 180 bacteria;
Illinois river, just above Grafton, 90 bacteria.

Bacteriologists mark a bacillus coli communis positive or negative. They mark it with a cross if the bacillus coli is present, and if it is not present, it is marked "minus." Zero means sample not examined for coli. By the word "present" I mean that it was a positive reaction; that it showed the coli communis were present in the sample. I found bacillus coli communis in it. (The letter B indicates the word "Bacteria.")

September 16:
Mississippi river, Chain of Rocks, 1700B;
84 Mississippi river, Madison Landing, 800;
Missouri river, near the mouth, 2600;
Mississippi river, 2 miles above mouth of Missouri, 700B;
Mississippi river, 1½ miles below Alton, 800B;
Mississippi river, 1 mile above Alton, 700 B.
September 21:
Illinois river, 1½ miles above Grafton, 450B;
Illinois river, 3 miles above Grafton, 400B;
Illinois river, 5 miles above Grafton, 425B;
Mississippi river, 1 mile above Grafton, 500B;

Mississippi river, 4½ miles above Grafton, 500B;
September 25:
Mississippi, Chain of Rocks, 3600B;
Mississippi, Madison Landing, 750B;
Missouri river, just above mouth, 5600B;
Mississippi river, half way between Alton and mouth of Missouri, 750B;
85 Missouri river, opposite Clifton, 750B;
Mississippi river, half mile below Portage, 600B;

Between September, 1899 and January 23, 1900, no bacteriological investigations were carried on by me to determine the presence of bacillus coli communis in the Mississippi or Illinois, other than above mentioned.

Above testimony is in regard to work done from August, 1899 to January 23, 1900, under my personal supervision, I doing the coli work personally, media made in my office, plating done at the Chain of Rocks.

Drainage Canal was opened six days prior to January 23, 1900.

Bear trap Dam was lowered January 17, 1900.

89 Beginning January 23, 1900, pursued bacteriological investigation in the waters of the Canal, Lake Michigan, the Illinois, Des Plaines and the Mississippi rivers.

90 Took samples of water from various points, studied it for its bacteriological points, that is the number of bacteria per cubic centimeter, for the detection of bacillus coli communis, and the study of the bacteriological flora of the water—that is the different species found in it.

Following are distances from St. Louis intake to points named:

Lake Michigan, 357 miles;
Lockport, 327 miles;
Joliet, 320 miles;
Peoria, 196 miles;
Grafton, 39 miles;

Alton, 23 miles;
Hartford, 12 miles;
All above towns are in Illinois.
Bellefontaine on the Missouri river, 14 miles.

92 Lowering of the dam at Lockport and the working of the pumps at Bridgeport changed the flow of the Chicago river—reversed it.

I collected samples of water daily at Lake Michigan, Lockport, Joliet, Peoria and Grafton, beginning 23d of January, 1900.

93 Our instructions were to take it from the channel where the water flowed the most rapidly and deepest, three feet below the surface with the apparatus designed by us.

Water was taken in Chicago at the four mile crib, Carter Harrison crib, ten miles from the Chicago shore, Lakeview, three mile crib, four mile crib, 68th street, four mile crib. The cribs are intakes for Chicago water supply:

Following is the time taken, place, number of bacteria, etc.
July 23d, 4 mile crib, 11:45 A. M., 1,600B.

94 Carter Harrison crib, July 30th, 11:30 A. M., 1900, 12,300B, ten feet below surface.

Ten miles from shore, ten feet below the surface, Aug. 9, 4 P. M., 16,300B.

95 Carter Harrison crib, 31st of August, 10:30 A. M., 21,400B.

Lake View crib, Sept. 7, 11:30 A. M., 5,200B.
Two mile crib, Sept. 15, 10:30 A M., 909,700B.
Three mile crib, Sept. 15, 11:45 A. M., 111,500B.
Two mile crib, Sept. 22d, 2 P. M., 61,000B.
68th St., Sept. 22d, 11:15 A. M., 44,000B.
Two mile crib, Sept. 28, 10:45 A. M., 11,300B.
Lake View crib, Sept. 28, 12:15 P. M., 3,100B.
Two mile crib, Oct. 11, 12:15 P. M., 1,100B.
Three mile crib, Oct. 11, 11:30 A. M., 1,000B.
Two mile crib, Oct. 19, 11 A. M., 4,400B.

Two mile crib, Oct. 19 11 A. M., 4,400B.

Three mile crib, Oct. 19, 10:30 A. M., 1,100B.

96 Four mile crib, Oct. 26, 11:45 A. M., 90,000B.

68th st. crib, Oct. 26, 12:30 P. M., 157,500B.

68th st. crib, Nov. 9, 11:30 A. M., 3,300B.

Four mile crib, Nov. 9, 11 A. M., 2,900 B.

Sample taken Oct. 11, at the two mile crib and contained organisms of bacillus coli communis—bacillus delicatulus, bacillus fluorescens incognitus; bacillus helvolus; bacillus proteus mirabilis; bacillus pyocyaneus; bacillus stellatus bacillus superficilis; bacillus viridis.

All these bacteria are harmless except the bacillus coli communis—except when injected beneath the skin. It is harmless in the individual except when it goes down into the appendix and causes appendicitis. Mucous membrane of the appendix is very delicate.

97 All these bacteria other than the bacillus coli communis are inhabitants of fresh water, both lake and river. Their presence other than the coli does not indicate the absence or presence of sewage.

Next examination was made on the Drainage Canal at Bear Trap Dam, March 3, and continued daily until October 9, 1900. And from September 26 to November 25, 1901.

There was a very great bacteriological variation or fluctuation in the examinations at this point. It ran from millions of bacteria per cubic centimeter down to a few thousand. This depended on the amount of sewage from Chicago discharged in the canal. 98

During the first period of time above stated, this examination disclosed the presence of coli bacillus. This bacteria was found in 87 per cent of the samples collected.

In March, 1900, it was found in 72% of the samples. May, June and July, 87%. Aug., Sept., and October, up to the 10th, 100%.

From Oct. 5, to 27, 1901, 81.2%.

Made a microscopical examination of the waters of the canal at this point. Samples were submitted to Mr. Johnson and to Mr. George C. Whipple, of New York.

We separated out a number of micro-organisms at these different periods. Inasmuch as bacteria belongs to the vegetable kingdom, we speak of the bacteria found in water as
99 the basterial flora of that water. It means the class of schizomycetes, order thelophyta.

Four sets of ten organisms each and 80 at another time, were found at Bear Trap Dam. Sets of samples were collected Sept. 16, May 31, June 14, and July 9, 1900. Eighty organisms were isolated from the water during the months of October and November, 1901.

Second investigation was from March 3, to Oct. 11, 1901.

Following is water taken from the Chicago Drainage Canal before the water passed over the Bear Trap Dam at Lockport, Illinois. (See table.)

"Not found," and "absent" means the same thing; it
107 means that in examining a quantity of water that we did not detect the presence of the bacilli. It does not mean that it was not there, but it means that they were unable to find it.

An examination of a biological character, of the water in the Des Plaines river at McDonough street bridge, Joliet, which is in the body of the city. Some of the sewage from the penitentiary and from the iron works comes in above this point. This was made from March 3d, until October 24, 1900.

The bacillus coli communis was found in 73% of the
108 samples collected daily at McDonough street bridge in the five months, March to July, inclusive. This organism was found in 64% of the examinations made. In August 78%; Sept. 1st to October 9th, inclusive, 99% of the time.

The third period, or the Ruby street bridge, 83.3% of the time, and at Brandon's bridge, also in Joliet, 79.2% of the time. That was in the third period.

The third period extended to Oct. and Nov., 1901.

109 The results March 3, at Des Plaines river, McDonough street, Joliet. (See table.)

114 On the 17th of Oct., determination made, 16,000 coli present; Oct. 24, 146,000 coli present.

115 Made examination as to the bacteria flora and located 17 distinct species—isolated, as follows:

Albus; aquatillis, sulcatus No. 1; aquatillis sulcatus No. 5; cloacae; coli communis; delicatulus; fleuresens tenuis; helvolus; iridescens; lacti viscosus; liquefaciens; ocracous; proteus mirabilis; proteus zenkeri; stellatus; superficialis sarcina lutea.

These were found during the investigation of 1900. Next point material was collected was at Peoria, above Peoria, 120 miles from Joliet.

116 Peoria is on the Illinois river, which is formed by the joining of the Des Plaines and Kankakee rivers at a point 23 miles below Joliet. At La Salle, 102 miles below Chicago, the Vermilion river comes in and the Illinois and Michigan canal. Investigation was made at Averyville, below Peoria.

118 There was a great variation as to the number of bacilli at Peoria. They seemed to fluctuate somewhat during the seasons, to very high numbers at the Bear Trap Dam. There seems to be a perceptible rise in the number of micro organisms at Peoria at this period. Coli bacillus was found in 75% of the daily tests made. Samples were taken in the stream where the current was running fastest. This was the second period

119 beginning January 23, 1900, to October 9, 1900. (See Table.)

126 Examination made at Grafton, Illinois, 163 miles below

127 Peoria. From January 23, to October 9, 1900, two miles above Grafton. (See table.)

134 Bacterial flora of the Illinois river just above Grafton, Illinois—species: (See Rec. 134.)

Quantitative examination of Mississippi river, 3 miles above Grafton. (For result see table and Rec. 135.)

143 Bacterial flora of the Mississippi river just above Grafton, Ill.

144 Samples taken from Mississippi river, one mile above Alton, below the mouth of the Illinois river.

Coli bacillus was found in 52% of the tests made for it in this period.

Result of quantitative examination of waters of Mississippi river at above point. (See table and Rec. 145.)

Bacterial flora found in the Mississippi river one mile above Alton.

Hartford is in Illinois, 7 miles below Alton and one mile
153 above Missouri river where it empties into Mississippi.

Bacteriological examination made at Hartford, Illinois. A boat was sent out in the middle of the stream and samples collected. Coli bacillus was found in 61% of the daily samples collected. This is a slight increase over the average in which this organism was found at Alton—52% at Alton and 61% here.

The results of the quantitative determination of bacteria in the Mississippi river opposite Hartford, Illinois, together with the results of tests for the bacillus coli communis, was as follows: (See table. Also Rec. 153.)

Bacterial flora of the Mississippi, opposite Hartford, Illinois, 1900.

161 Bellefontaine is situated on the Missouri river, six miles above the mouth, on the Missouri shore—the south shore. Result of examination made there is as follows: (See table and Rec. 161.)

168 Bacterial flora of the Missouri river opposite Bellefontaine, Missouri, covering the period from January 24, to October 25, 1900, as follows:

Three separate examinations were made at the Chain of Rocks, known as the Missouri shore, the intake, and the Illinois shore. Missouri shore was taken about 300 yards from the shore in the channel on the Missouri side of the stream.
169 The intake sample was taken from a boat out in front

of the intake, just above it. The third sample was taken in a line with it over toward the Illinois shore.

Bacilli coli communis was found in 58% of the daily samples collected at the Missouri shore.

Following is result of the quantitative determination of the bacteria in the Mississippi river water near the Chain of Rocks near the Missouri shore, together with results for the tests of the bacillus coli communis—bacteria per cubic centimeter: (See table and Rec. 170.)

175 Bacteriological character of the Mississippi river water at the Chain of Rocks near the Illinois shore, about 300 yards from the shore, in the channel. The coli bacillus was found in 68% of the samples collected at this point during this period. (See table and Rec. 178.)

186 Coli bacillus was found in 62% of the daily samples taken at the intake at the Chain of Rocks.

Bacteriological examination of the water is as follows:

194 Bacteriological flora of the Mississippi river at the intake tower:

195 Samples of water were collected for analysis from basin No. 3, the water having rested 70 hours. This basin has a capacity of 29,000,000. Quantitative determination of sample from reservoir, Chain of Rocks, varies somewhat. Each reservoir has a capacity of 29,000,000. There are six of these basins.

Average number of bacteria in samples collected during the second period was 56% of the number found in samples collected at the intake tower. 44% of the bacteria in the water taken into the reservoir, therefore, were removed by this

196 70 hours subsidence—by this sedimentation. We don't care to say anything about the third period at all.

When the water goes into these reservoirs it is not absolutely quiescent, but it is the water flowing from one end of the large reservoir to the other in 70 hours. The only movement of the water is that caused by it flowing into and on through the reservoirs. The time it is in transit across the reservoir would be about 70 hours.

When I refer to the intake tower, I refer to samples taken just above the intake tower. At that point the coli bacil-
197 lus was found in 65% of the daily samples collected. That is inside the tank in the reservoir, after 70 hours sedimentation. Results of quantitative determination of bacteria in samples of water collected from the reservoir at Chain of Rocks, as follows: (See table and Rec. 197.)

204 Water was collected at the old city hall, from a tap. The city hall is on 11th street, between Market and Chestnut streets. It gets its supply from these reservoirs.

Water from the Mississippi river at the Chain of Rocks passes through the settling basins, then through an 11 foot conduit to the high service pumps at Baden, which is situated 4½ miles from the Chain of Rocks. Then it is pumped into
205 the stand pipe located at Compton Hill reservoir, and distributed to the western part of the city, while the remainder flows through a 9 foot conduit and empties into four reservoirs at Bissell's Point. Each reservoir has a capacity of 15,000,000 gallons, and while the actual periods of subsidence of the water in these reservoirs can not be ascertained definitely, it is stated to be three or four days on the average. No samples were collected from these basins. We did that in the later period. From these reservoirs the water passes into the distributing system of the city. The water is turned into the stand pipes at the foot of Grand Avenue, and distributed to the eastern part of the city in which the old city hall is located. That is the low service pumps.

It is 3 miles from the city hall, as the crow flies, to Bissell's Point, and from there it is here recorded, the distance, I just gave you, 4½ miles from Baden, and so many miles from Chain of Rocks. This is northwest of the city.

During this period the average percentage removal of bacteria, found on comparing the results obtained from samples collected at the intake of the St. Louis water works, Chain of Rocks and the tap in the bacteriological department of the old city hall, respectively was 90 per cent.

206 That is 90 per cent of removal from the intake between those points.

The bacillus coli communis was found in 71 per cent of the samples collected during the period from May 1st to October 31st, 1900.

Results of quantitative determination of bacteria and results of tests for bacillus coli communis from samples taken at the old city hall, 11th and Market streets, beginning May 11, when we moved into this laboratory, together with the results of tests for bacillus coli communis per cubic centimeter:

(See table and Rec. 206.)

211 Bacterial flora of water taken from the tap of the bacteriological laboratory, old city hall, St. Louis, Missouri, May to October, 1900.

In July, 1901, a motion was adopted by the Municipal Assembly ordering a third investigation of the city water
212 supply to be taken. This period of investigation embraced the work done between August 26 and December 1, 1901.

Temporary bacteriological laboratories were established and equipped with the necessary apparatus at the following points:

First, at Joliet, Illinois, 306 N. Joliet st., under Dr. W. C. C. Kirchner.

330 Second, Y. M. C. A. bldg., Peoria, Illinois, Dr. Wm. H.
386 Rush in charge.

Third, at Grafton, Illinois, in the Dempsey House. Mr. Leon G. Tedesche, in charge.

1141 Market st., St. Louis, with 5 assistant bacteriologists, under charge of witness.

Samples were collected from the following points:

Des Plaines river, above Lockport, from October 5, to November 25, 1901. That sample was collected about two miles up the river, above its junction with the drainage canal so there would be no backwater in it.

213 Drainage canal, Bear Trap Dam, above dam, September 25, to November 25, 1901.

I. & M. Canal, 9th St. Bridge, Lockport, Illinois, September 25 to October 30, 1901.

Drainage canal, 9th St. Bridge, Lockport, Illinois, October 2 to November 26, 1901.

Drainage canal below Rubey St., Joliet, September 25 to November 26, 1901.

Drainage canal, Brandon's Bridge, Joliet, September 25 to November 26, 1901.

Illinois river, what is known as Shady Beach, about 3 miles above Peoria, Illinois, October 1 to November 27, 1901.

Illinois river, above railroad bridge, Pekin, Ill., October 1 to November 27. This station is five miles below the lowest Peoria sewer.

Illinois river, Kingston, 3 miles below Pekin, Ill., October 4 to November 27, 1901.

Illinois river, 3 miles above Grafton, Illinois, October 4 to November 27, 1901.

Mississippi river, two miles above Grafton, Ill., October 4 to November 30, 1901.

Mississippi river, one mile above Alton, Illinois, October 5, to November 30, 1901.

Mississippi river, opposite Hartford, Illinois, October 5, to November 30, 1901.

214 Missouri river, opposite Ft. Bellefontaine, October 4, to November 30, 1901.

Mississippi river, Chain of Rocks, near Illinois shore, September 14 to November 30, 1901.

Mississippi river, Chain of Rocks, near the Missouri shore, September 14 to November 30, 1901.

Mississippi river, intake tower, September 14 to November 30, 1901.

Reservoir at Chain of Rocks, September 15 to November 30.

Reservoir, Bissell's Point, September 16 to November 30.

Tap laboratory, 1141 Market st., St. Louis, September 17 to November 30, 1901.

Tap, residence, 5946 Garfield avenue, Oct. 2 to November 30, 1901.

Seven samples were collected at La Salle, Ill., from the Illinois, and 24 at Beardstown, Ill. Both samples were sent to Peoria, packed in ice for analysis.

Mr. Randolph, chief engineer of the Sanitary District, constantly spoke to me of the Des Plaines river between Lockport and Joliet as being the canal—the drainage canal.

215 Des Plaines river at Lockport, 2 miles above its junction with the drainage canal water, there were forty samples taken.

Drainage canal, Lockport, above Bear Trap, 52 samples were collected.

216 Illinois & Michigan Canal, Lockport, 9th st. bridge, 34 samples.

Drainage canal, 9th st. bridge, Lockport, 41 samples.

Drainage canal, below Rubey st., Joliet, 6 or 7 miles from 9th st. bridge, 51 samples.

Drainage canal, Brandon's bridge, 49 samples.

Brandon's bridge is 40 miles below this Rubey street sample, so that would be about 12 miles from the drainage canal.

Illinois river, Shady Beach, above Peoria, 54 samples. That is 120 miles down the river. About 3 miles above Peoria.

Illinois river, above railroad bridge, Pekin, Ill., 57 samples. It is ten miles from the center of Peoria to the center of Pekin. It is five miles below here—below the last sewage discharge from Peoria into the Illinois river.

217 Kingston, 3 miles below Pekin, 55 samples.

Illinois river, three miles above Grafton, 56 samples.

Mississippi river, 2 miles above Grafton, 56 samples.

Mississippi river, 1 mile above Alton, 52 samples.

Mississippi river, opposite Hartford, 51 samples.

Missouri river, opposite Ft. Bellefontaine, 55 samples.

Mississippi river, Chain of Rocks, Illinois shore, 74 samples.

Mississippi river, Missouri shore, 72 samples.

Mississippi river, intake tower, 70 samples.

Reservoir, outlet screen chambers it is called, Chain of Rocks, 75 samples.

Outlet screen chamber is located about the middle of the end of the reservoir, facing south, and the water discharges out of this hole in the wall through a screen, and consequently they call it the outlet screen chamber. About 300 or 400 feet
from the Mississippi river.

218 Bissell's Point, 72 samples.

Tap laboratory, 1141 Market st., 69 samples.

Tap, 5946 Garfield avenue, 59 samples.

Illinois river, La Salle, 7 samples.

Illinois river, Beardstown, Illinois, 24 samples, making a total of 1,215.

The work during this period was done under my supervision.

Samples collected from the canal at Lockport and the river at Peoria were taken at once to the laboratory, placed on ice and plated without delay. This is true of all of these samples that were collected at points where laboratories were established. In St. Louis a room was secured from the water commissioner at the Chain of Rocks pumping house, and there the samples were collected in the river for the Chicago experts—a Chicago and a St. Louis bacteriologist, at the same time and place, brought ashore and both bacteriologists plated in this same room, so they were plated immediately there when they came ashore. Facilities were furnished by the city at time of taking these samples. I believe Chicago paid for some of the
heat.

218 The samples were just brought to the laboratories of both
parties, brought to 1141 Market st., by Mr. Damon, who did this plating at the laboratory of the Chicago expert, some-

where on Locust street, both going in and out together.
219 These samples were collected by both parties at the
same place—they went out together. They were collected with an apparatus designed by myself in wide mouthed, sterile flasks, at 3 feet below the surface. Same manner and same apparatus were used as were used in second period. The temperature of the water and air were taken at the same time with a thermometer that was a part of the apparatus; 2,325 samples were collected at the various points noted above, and analysis for quantitative determination of bacteria and tests made for bacillus coli communis.

We also investigated the bacterial flora of the water. Besides that a systematic study of the flora was made by an expert microscopist, Mr. George C. Whipple, of Brooklyn, N. Y.

We separated out eight sets of ten organisms each—separated out in pure culture, and 80 organisms in each station.

The sample collected once or twice a weak, was plated according to the method described in the first period, and then ten organisms were selected from that plate, always trying to select an organism that was new to the bacteriologist. He selected the first ten that were familiar to him and the next time he went over that plate he tried not to select any of that same
form, the idea being to try to find all the different species
220 of micro-organisms in that particular water. When a
colony was seen to be different from the others, it was picked out and picked up and thrown on agar agar. If the culture proved to be a pure one, then it was shown in a variety of media to detect it, to ascertain its cultural characteristics.

The results were recorded on a chart that was original with our laboratory. Then those charts, 300 of them, some 30 different varieties of media, were used.

Experiments in this period were carried on in the same manner and according to the same rules laid down for the first
period.
222 Result of examination above Bear Trap Dam drainage

canal, Lockport, Illinois, beginning September 26, as follows: (See table and Rec. 222.)

224 Illinois & Michigan canal, 9th street bridge, Lockport, Illinois. I took some samples from this canal to see what were the numbers in that also, because the Chicago sewage is being dumped into that from the south fork of the Chicago river. This is not the Chicago Drainage canal.

Results are as follows: (See table and Rec. 224.)

225 Quantitative determination of bacteria per cubic centimeter and the detection of the bacillus coli communis in the Drainage canal, just below Rubey street, Joliet—it is really the Des Plaines river. (See table and Rec. 225.)

227 Des Plaines river, Brandon's bridge, below Joliet, beginning September 26, as follows: (See table and Rec. 227.)

228 Des Plaines river two miles above the conjunction, with the effluence of the Chicago Drainage Canal. (See table and Rec. 229.)

230 Drainage canal and Des Plaines river at 9th street bridge, Lockport. (See table and Rec. 230.)

230 Drainage canal, 9th street bridge, Lockport. (See table and Rec. 230.)

231 Coli communis was found in 73 per cent of the samples collected daily at McDonough street, Joliet. That was in the second period we have just mentioned. That was given day before yesterday.

At Rubey street, 83% of the samples. That is the Des Plaines river at Joliet and at Brandon's bridge in 79% of the samples examined.

232 The next examination made, the laboratory was established at Peoria in the Y. M. C. A. building, and a few samples were collected at La Salle, in the Illinois river, and samples taken daily from the river at Peoria. These examinations were made immediately and they came to the laboratory immediately and were plated. That was at Peoria, below Peoria, at Pekin, and at Kingston, and further down, Beardstown,

samples were collected and sent back to the Peoria laboratory encased in ice.

At Grafton they were plated and examined right there.
233 The coli bacillus was found in October, 1901, in 87.1 and in November 79.1 per cent above Peoria at Shady Beach.

Quite a number of rivers enter into the Illinois river between Joliet and Peoria. The distance between Joliet and Peoria on the Illinois river is 120 miles. We have the Du Page, forming with or joining the Des Plaines river to form and join the Kankakee. The Fox comes in from the north, and the Vermilion from the south. I have viewed all these rivers but the DuPage. From Mr. Harmon and Mr. Cooley's figures I
234 find during the low water stages of October, 1889, the Des Plaines flowed per cubic feet per second, 13.21; the DuPage 32.77; the Kankakee, 509.24; the Fox, 329.95. He has the Vermilion marked here, 4, which is wrong because the Vermilion is a very much larger river than the Des Plaines.

At this particular time last year when this examination was going on, the water was particularly stagnant and very little water flowing out of it. That is out of the canal, the I. & M. canal, into the Illinois river.

235 The samples collected at La Salle were packed in ice, after being collected with the apparatus which is described, by a man employed there, collected above the point of discharge of the I. & M. canal into the Illinois river, so as not to have the effluence of the I. & M. canal mixed with this water. They were at once shipped to Peoria by express and examined there as soon as it arrived.

Water from Shady Beach, three miles above Peoria, was immediately carried to the laboratory in the Y. M. C. A. building at Peoria. Pekin sample was carried directly to the laboratory at Peoria.

Result of examination made at La Salle is as follows:
236 October 28, 1901, 7,500 coli present.
October 29, 16,500, absent.

November 15, 9,000.

Coli tests not made in the November samples at this point.

November 16, 38,000.

November 17, 19,500.

November 18, 13,500.

November 21, 68,500.

Three miles above Peoria, the results of the examination were as follows: (See table and Rec. 236.)

238 Pekin bridge, Pekin, Illinois. These samples were taken to Peoria on the same day. There is a street car that runs from Pekin to Peoria.

This is five miles below the Peoria sewage. It is above Pekin. It is above the railroad bridge, in the channel at Pekin, Illinois. (See table and Rec. 238-239.)

240 At Kingston, in the channel, three miles below Pekin. The sample was obtained and the test made at Peoria, traveling by train, a few minutes after being taken it was plated.

These samples were taken well below Kingston. The river was low during this time and a man drove down in a buggy as far as he could drive and collected his sample.

Results were as follows: (See table and Rec. 241.)

242 At Beardstown the sample was taken in the river above the town, right out in front of it. The samples were packed in ice and shipped to Peoria where they were examined in the bacterial laboratory by Dr. Rush. It would take but a short time to get the samples to Peoria, Beardstown being a couple of hours by train. Most always made the same day. I didn't superintend that part of it. But I saw it was working right. I had general charge of it traveling up and down from those points.

243 Result of that examination was as follows: (See table and Rec. 243.)

244 Next examination was made at Grafton. A laboratory was established in the Dempsey House, under the charge

of Mr. Leon G. Tedesche. Grafton is about 160 miles below Peoria.

245 In October, 1901, the percentage of coli bacillus found in the samples was 53.6—for both November and October, 53.6.

For October, 1901, the coli was found in 53.6% of the cases, and for November, 29.17% making an average of 45%.

These samples were taken and examined the same day. The laboratory was three miles from the place of taking on the Illinois.

They were taken in the middle of the stream, in the current, three feet below the surface, with this same apparatus I have testified about, and the same precautions were used and the same instruments were used.

246 The results were as follows: (See table and Rec. 246.)

247 Next was an examination of the waters of the Mississippi river two miles above Grafton, in the channel of the river, selected the same as the water selected in the Illinois above Grafton, with same apparatus and precautions.

The results of the examination were as follows: (See table and Rec. 248.)

249 In October, the percentage of instances in which the coli was found in the Mississippi river above Grafton was 33.33; for November, 62.50; total per cent 47, for two months. Those two rivers run very uniformly.

Samples were taken at Mississippi river, at Alton, one mile above Alton; Mississippi river at Hartford, Illinois; Missouri river, Ft. Bellefontaine; intake tower, Chain of Rocks; Illinois shore, Chain of Rocks; Missouri shore, Chain of Rocks; outlet screen chamber reservoir, Chain of Rocks; outlet
250 stream chamber; basin, Bissell's Point; tap in city chemist's office, 1141 Market st., tap at 5946 Garfield avenue.

First samples of water during this investigation were taken at the intake tower, beginning at St. Louis, September 14 and from that on until November 30. The samples from the Missouri river at Ft. Bellefontaine, Mississippi river at Hartford, and Mississippi river at Alton, began October 4, October 5, October 6, rather, for Hartford, Illinois; and October 5, for Alton.

One mile above Alton, began on October 5, 1901, taken in the channel of the river, from a boat, taken ashore and brought back to St. Louis, carried there by the collector, the same day they were collected. Collected at ten o'clock and arrived at the laboratory about two, packed in ice, and plated at once.

The results were as follows: (See table and Rec. 251.)

252 Mississippi river at Hartford, Illinois, which is six or seven miles below Alton and one mile above the mouth of the Missouri river where it empties into the Mississippi. Hartford is 6 or 7 miles below Alton. These samples were sent to St. Louis. They reached the laboratory about 2 o'clock and plated immediately.

The result of the investigation was as follows: (See table and Rec. 253.)

255 Missouri river at Ft. Bellefontaine, six miles above the mouth of the Missouri where it empties in the Mississippi. Commenced taking samples October 4. Collector got the sample about 10 o'clock in the morning, reached the laboratory about two o'clock—between noon and two o'clock.

Results were as follows: (See table and Rec. 255.)

257 At the intake, Chain of Rocks, a cross session was taken by drawing a line across the river from shore to shore through the intake. The intake sample was taken in front of the intake tower anywhere from 100 to 300 feet in front of it, as the man rowed across the river. The first sample was taken 300 yards from the Missouri shore, and the third sample from the Illinois shore, 300 yards from the shore in the channel. The samples were taken ashore and plated immediately, and
when the plates were hard were carried to the bacteri-
258 ological laboratory at 1141 Market st., and there incu-
bated, and counted when ripe.

We will begin with the Missouri shore sample, 300 yards from the Missouri shore, just above a line drawn through the intake. You see it is impossible to get a sample below there because it is rocky—a chain of rocks has been thrown out into the river to deflect the water away from the shore, so it would be shallow water below the chain of rocks; consequently the samples were taken above the Chain of Rocks, where the water was deep.

The results were as follows: (See table and Rec. 258.)

259 Missouri shore, Chain of Rocks, result was as follows: (See table and Rec. 259.)

260 Illinois shore, Chain of Rocks, the result was as follows: (See table and Rec. 261.)

263 At the intake the samples were taken at the intake tower from 100 to 300 feet above the tower in the river where the river was running fast. This was not taken from the intake tower itself. The intake tower is 1,500 feet from the shore, and the samples were taken in the channel in front of it. It is difficult to take a sample in a tower, because the water is pouring into it from all sides, and it is very difficult for a man to get down there.

The results were as follows: (See table and Rec. 263.)

265 Outlet screen chamber, Chain of Rocks is in the reservoir, after 70 hours rest in the reservoir. It compares about the same with a year ago, or a little bit better during that time. I think there wasn't so much bacteria in the water.

Samples were taken from the same place as in period number two. They were taken as soon as collected, to the house or pumping station here and plated immediately. The plates were put into a special apparatus designed by Mr. Damon and carried to the city chemist's office, 1141 Market st., and there incubated and counted afterwards.

Results were as follows: (See table and Rec. 266.)

268 Next samples were taken from the water in the settling basin at Bissell's Point—out of the settling outlet where the water was flowing out into the deep well that they have there. The results were as follows: (See table and Rec. 268.)

270 At the tap in the city chemist's office, 1141 Market st., the water was allowed to run five minutes before the sample was taken in a steriled flask and plated immediately. The results were as follows: (See table and Rec. 271.)

273 At the tap at 5946 Garfield ave., which was the residence of one of our bacteriologists, Mr. Snodgrass, the water was supplied from the Compton Hill reservoir stand pipe or from the high water service at Baden. It is about four miles directly across there, but you see it first come to the stand pipe and goes back to him, so it must have traveled six miles to the stand pipe and received its pressure there, and then was carried out to this district.

274 It traveled six miles to the stand pipe and about four miles from the stand pipe to his residence. That would be about ten miles.

The samples were brought immediately from the tap to the laboratory where it was plated. The results of that examiation were: (See table and Rec 274.)

275 The percentage of coli at each one of these places was, 1 mile above Alton, Ill., coli for October, 1901, 100%; November, 1901, 77%, making an average of 88.6 of samples collected.

276 Hartford, for October, 1901, 86.4%; November, 56%; average 70%. Hartford is seven miles below Alton.

Bellefontaine, October, 1901, 92.6; November, 1901, 80%; avreage of 86.2.

Missouri shore, Chain of Rocks, September, 76.9; October, 97%; November, 84.6; average for this period is 88.4.

Chain of Rocks, Illinois shore, percentage of coli for September, 1901, 76.9; October, 97%; November, 77%; average is 81.7.

Intake tower, Chain of Rocks, September, 1901, 76.9% October, 90%; November, 77%; average 80%.

Reservoir, Chain of Rocks, after sedimentation, September, 1901, 83.5%—there is something wrong in this typewritten copy here and I will have to go over the results. I will go over those calculations tonight.

277 Outlet settling basins, Bissell's Point, September, 86.4; October, 94.04%; November, 93.8%; average 91.41%.

Tap at 1141 Market st., September, 85.7%; October, 97%; November, 80%; average 87.5%.

Average of bacteria at the Chain of Rocks intake for September, 14 days, is 2,686. This has no reference to the bacilli coli communis. That was at the outside of the intake in the river.

Outlet screen chamber settling basins, Chain of Rocks, after passing through the reservoir, 1,375 is the average, 14 days, after settling 70 hours, or the percentage removal of bacteria is 48.43%. The average for 14 days at Bissell's Point, outlet of the basins, the number of bacteria is 363, or the per centage of bacterial removal after passing through both reservoirs, is 86.05%. That means the loss of bacteria in the one reservoir and before they go out of another; that means 86.05 per cent have been removed to the outlet chamber of the second reservoir, from the intake. Now then, the removal to the
278 tap, 300—the number of bacteria removed per cubic centimeter, average 14 days, is 300. Percentage of removal is 88.83.

October average number of bacteria for the month is 20,500, at the intake in the river. The average number for October in the outlet screen chamber in the settling basin at the Chain of Rocks is 2,975. Percentage removal for this month is 85.6.

Bissell's Point, outlet of the basins, the number of bacteria averaged for the month, 1,137. Percentage removal, 90%.

Average number of bacteria for October at tap 1141 Market st., 843. Percentage removal 95.9%.

Average for month at 5946 Garfield ave., the tap, 412; per centage removal, 98.

November, total number of bacteria found at the intake, average 39,518.

Outlet screen chamber, Chain of Rocks settling basins, November, 7,600. Percentage removal, 81.5.

Bissell's Point, outlet settling basins, average number of bacteria per month, 2,545; percentage removal, 93.5.

Tap, 1141 Market st., average is 2,560; percentage removal 93.2.

5946 Garfield ave. tap, average number for month 2,880. This is more than the other place and I don't know how to account for it except that they were stirring things up in the pipes.

Percentage removal is 92.7, or I can give total percentage lost for those three months, which is 14 days in September all of October and all of November, at the outlet of the seven settling basins, and the outlet screen chamber, Chain of Rocks, 71.84 per cent.

279 Bissell's Point, outlet settling basins, 90%.

Tap, 1141 Market st., 92.64%.

Tap, Garfield ave., 95.3%.

Mississippi river, above Grafton, average number of bacteria per cubic centimeter for October, 1901, 717.

For November, 2,290:

Illinois river above Grafton, for October, 1,780; for November, 3,050.

MR. JEFFRIES: Now give us the result of the cultural and bacterial features of the bacteria found in the Illinois river, the Mississippi river, the Missouri river, Lake Michigan 280 and the Canal—that is the Chicago Drainage Canal during the second period from January to October, 1900.

A. Now this is a chart original with this laboratory, presenting the morphological, cultural and biochemical features of the micro-organisms found in the waters of Lake Michigan, the Chicago drainage canal, the Illinois river and the Mississippi river at the intake.

The bacteria here are classified into types according to the colors which they produce upon the media, or certain other characteristics by which they can be confined to groups, distinctive groups, and the morphological, cultural and biochemical features which carry it through a variety of media.

We have on the fluorescens type first, the bacillus fluorescens incognitis. The first investigator was Wright—he first discovered it or found it in the water. It is a bacillus, motile, does not form spores. Under cultural feature now: in nutrient broth it produces a scum and the nutrient broth is made
281 turbid by it. In an agar tube it shows a wrinkled membrane.

Gelatine plate colony characteristic, not distinct.

Potato, a luxuriant and visible growth.

Fermentation tube does not produce gas.

Grows best at body temperature.

In gelatine it does not liquefy.

In milk it does not coagulate.

It does not liquefy blood serum.

It does not ferment.

It produces no gas.

Does not reduce nitrates.

Does not produce indol.

Again it does not coagulate milk.

Is chromo-genic on nutrient agar, and it produces fluorescens of the media.

Body temperature is a negative temperature, 98 3-5 or 36½ centigrade.

By developing I mean it grows best on our nutrient media, more vigorous in a definite period of time.

282 We have two words in bacteriology, aerobic and anaerobic. Aerobic bacteria grow best in the presence of oxygen. The an-aerobic bacteria grow best in its absence. Now there are classes of micro-organisms that grow under both conditions. They grow nearly as well under an-aerobic conditions as they do under aerobic conditions. Since they have this faculty of doing this thing they are called facultative an-aerobic

of facultative aerobic, depending upon which condition they grow best.

Indol is one of the products, one of the putrefied products of the result of destructive composition or the destructive action of bacteria upon organic matter.

307 Under the head of morphology we have here the question of the form of the micro-organisms—bacillus meaning a rod, and it is marked here either positive or negative. If it is bacillus positive, it is marked with a cross—positive; if in any other form than bacillus, it is marked negative, with a minus sign.

The next under morphology comes the diameter greater than 1M. "M" is for the Greek word Micron and micron is one 1-1000 of a millimeter, or 1-25,000 of an inch, so that a
308 micro-organism here recorded will be larger or smaller than 1-25,000 of an inch, according to this chart.

Then comes motility. A micro-organism may be motile, that is, swim about, or it does not do so.

Under morphology comes the word spore which means that these micro-organisms contain within themselves bodies for the preservation of the species, so that the chart is marked positive and negative whether it be present or absent.

Under cultural features are the growth characteristics, with the certain nutritive media which will be named as we approach them.

Nutritive broth, that is nutritive broth as will be described, in test tubes, and into that the micro-organism is sown. Now it grows in that medium or it does not grow, and it grows in a certain way. If it grows in the medium making a cloudy condition in the medium that is recognized as turbidity. Then if the micro-organism grows out on the surface of the medium, forming a pellicle or membrane on it, it is called a scum and here so recorded. And if it is either one of these it is marked positive and if neither one, negative.

Under cultural features also comes nutrient agar-agar, of a definite percent in nutrient broth. This material is a solid medium and is slanted in the tube, and on the surface of that medium is sown the micro-organism in pure culture. Now the micro-organism grows and whether it grows with a dull growth, it is practically not transparent or translucent, and if the growth be wrinkled, it is so recorded here. If it does neither one, it is marked negative. If it grows dull or wrinkled, it is so marked.

The third feature is growth in gelatin plate. The micro-organism in pure culture is plated as described, generally in a petri dish, and this allowed to grow at 20 centigrade or about 60 degrees Fahrenheit. The growth that occurs here is called a colony which is a growing out of the micro-organisms into
numbers sufficiently large to be seen either with the un-
309 aided eye or with the microscope. The colony has cer-
tain characteristics. These are marked as its appearance
is characteristic or as it is not characteristic.

309 On potato, that is a potato cut into cylinders and then
crosswise, so as to slant, it making a surface upon which growth can be easily made. Upon the steriled potato then is sown this micro-organism and the micro-organism grows either with visible growth or with invisible growth, and the growth is luxuriant or not so.

Under cultural features we have fermentation tubes. Now the question is whether a micro-organism in this fermentation tube, which is a "U" tube, grows in the closed arm or not. The heating of media in these fermentation tubes dries the air out of it, so that the medium in this closed arm is practically free from air, consequently a strictly aerobic or so called obligatory aerobic will not grow in that arm, while one that is facultative, or has the faculty of growing in the absence of any oxygen will grow.

Then we come to the biochemical features we have here recorded, growth at body temperature. Now the micro-organism is sown upon agar-agar as a rule, and kept at the incubated temperature of the body, that is 98 3-5 degrees Fahrenheit, or 36½ degrees centigrade, or it is kept at 20 degrees entigrade, which is the ordinary temperature of about 60 degrees Fahrenheit.

Now, at which of these temperatures it grows best is here recorded, so that if it grows at body temperature—if it grows at that temperature best, it is marked positive. If marked negative, it does not grow that way best, while at that temperature. It does not mean that it does not grow at all, but that it does not grow so well as it does at the temperature below.

310 Affected by range of reaction, that was omitted in my testimony this morning, that means whether it grows in the presence of alkali, neutral or in the absence of an alkali or acid. We have first a medium alkaline to phenol phtalein 1.5%. Now in making up these tables I did not record that fact and that was omitted in my testimony this morning.

A second medium neutral to phenol phthalein, and a third acid, 1.5 per cent to phenol phthalein. Upon these three media the micro-organism is sown and the luxuriancy with which it grows indicates the reaction at which it best grows, alkaline, acid or neutral.

Under biochemical we have liquefaction, and we have first liquefaction of gelatin. Some micro-organisms have the faculty of digesting gelatin and liquefying it, and this is so recorded. It either liquefies or it does not liquefy. That is quite a cultural characteristic of these organisms, of most of these organisms.

The next feature is casein. The word "casein" is next used, which is the cheese of milk. Some micro-organisms have the faculty of growing in milk, precipitating the casein and reducing it to a liquid, others have not, so that is recorded.

The micro-organism is sown upon blood serum collected and sterilized in test tubes with the slanting surface, and kept at room temperature for 12 days, and if the micro-organism liquefies that blood serum, it turns it to a fluid, it is so recorded. If it does not do that, it is so recorded, positive or negative.

Dextrose broth—that means a nutrient broth prepared as we will show, with one per cent of dextrose, sugar, added to it. Now that is put in a fermentation tube and the micro-organisms inoculated into it. If these micro-organisms break up the sugar so as to form a gas in the closed arm of the tube, we speak of that as gas production, and it is marked positive. If it does not produce gas it is marked negative.

In the reduction of nitrates, a nitrate broth is made up
311 and in it the micro-organism is sown, nitrate broth I
should say, and if it reduces the nitrates to nitrites why that is so recorded, positive and negative.

Under the biochemical feature next is indol production. It is the result of destructive action of micro-organisms on organic matter. It produces a peculiar odor, a fetid odor, and whether it produces it or not, it is so recorded.

In milk sterilized in tubes, the micro-organism is sown. Now whether it coagulates the milk or not, it is so recorded, if it makes cheese. Then upon the nutrient agar-agar slanted in a tube, the micro-organism is grown, and whether it produces a color upon the medium or not, that is whether the bacterium itself has a color within its cell walls, that is spoken of as chromo-genesis, or pigment production. Fleurescent means that the toxines or whatever it may be which is produced by the micro-organism, colors the medium. The color does not remain within the micro-organism as impigment production, but it gives off a material which colors the medium itself. Then we have fleurescent coloration.

This chart is reproduced as Abstract Table No. 2 and will be found at end of this volume.

What I have testified to in reference to the bacterial qualities of this water in the forenoon and this afternoon is the result of practical experiments with the water under my supervision. Samples were collected from January 23 to October

11, 1900. Every micro-organism was separated out upon a gelatin plate which seemed to be different from the other micro-organism, and was first, after the agar-agar culture was obtained, sown in broth and its form and motility recorded from that. You see the bacterium undergoes three different transfers from the genatin plate to agar-agar, to get a good
312 growth of it, and then into broth so as to get as nearly as possibly constancy of form under these new conditions, and then here are recorded motility, size and form, and whether it contains spore or not and from this culture, if pure, all other cultural media was inoculated and recorded after a definite period of time. We were looking for constance of form and optimum reaction, and then recorded the results in books and then charted out as here shown.

In the sanitary examination of water there are several procedures, first the physical aspect of the water, that is, testing its temperature, its color, its turbidity, its sediment, its odor, hot and cold, that is the physical appearance. Then we have the chemical examination for the organic and inorganic constituents in the solution, and then the microscopical examination for the lower and higher forms of animal and vegetable life. Under the microscopical examination we have two kinds of examinations that will here be presented, first, the larger forms, what is known as the floating matter in the water, the animal and vegetable life, and known as plankton from planktos, the Greek meaning wandering. Then we have the so called bacteriological examination of the water which is an examination of the lower forms of vegetable life.

The history and method of microscopical examination of water is as follows: (Rec. 312.)

315 The samples of water for microscopical examination for Lake Michigan were collected first, July 23, from the four mile crib; next July 30, from the Carter Harrison crib, this is 1900. The third sample was collected August 9, ten miles out fro mthe Chicago shore. The fourth sample was

316 collected September 7th from the Lake View crib, and the fifth sample September 15th, from the two mile crib.

From the four mile crib the result is as follows: (Rec. 316.)

Carter Harrison crib July 30. (Rec. 517.)

Samples collected ten miles from shore, August 9, the result was as follows: (Rec. 318.)

Sample September 7, from Lake View crib, was as follows: (Rec. 319.)

From two mile crib, September 15th, as follows: (Rec. 320.)

Result of microscopical examination of the discharge of the Chicago Drainage Canal before it passes over the Bear Trap Dam at Lockport, Illinois, on dates named: (Rec. 321.)

Des Plaines river at Joliet on dates named. (Rec. 331.)

These samples were all collected at the same place as the bacteriological samples for this 1900 period.

Microscopical examination of the Illinois river two miles above Peoria, Illinois, taken out in the channel three feet from the surface. (Rec. 334.)

Microscopic examination of the Illinois just above Grafton, Illinois. Three miles above Grafton, as follows: (Rec 339.)

Mississippi river two miles above Grafton, as follows: (Rec. 342.)

Mississippi river one mile above Alton. (Rec. 344.)

Hartford, Illinois. (Rec. 346.)

Intake tower, St. Louis water works. (Rec. 349.)

353 This chart is a graphic representation of the number of micro-organisms found in the Illinois river at Grafton. It is a weekly estimation taken from the daily numbers in samples obtained of numbers of bacteria in samples obtained at this point, beginning January 23, in the year 1900 to October 9th. (Rec. 353.)

Mississippi river at Grafton, two miles above Grafton. (Rec. 355.)

Mississippi river at Alton, Illinois. (Rec. 356.)

Mississippi river at Hartford, Illinois: (Rec. 358.)

Mississippi river at Ft. Bellefontaine: (Rec. 359.)

Missouri shore, Chain of Rocks: (Rec. 360.)

Missouri—Illinois shore, Chain of Rocks: (Rec. 361.)

Intake tower, Chain of Rocks. In the river about one hundred feet in front of the tower, up the river: (Rec. 362.)

Outlet chamber, reservoir, at Chain of Rocks: (Rec. 363.)

Tap, laboratory at old city hall, 11th and Chestnut sts: (Rec. 364.)

Map received in evidence and marked complainant's exhibit No. 1: (Rec. 364.)

365 (Referring to complainant's Exhibit 1.)

This chart shows the bacteria per cubic centimeter. The numbers recorded perpendicularly along the profile lines. The weekly averages have been obtained by adding the bacterial contents, obtained from samples collected daily, dividing by seven, which gives the weekly averages. These weekly averages are recorded, beginning January 23d, and ending October 9th, 1900. They are recorded for the Illinois river at Grafton, Illinois; the Mississippi river at Grafton, Illinois; the Mississippi river at Alton, one mile above the town; the Mississippi river at Hartford, seven miles below Alton; the Missouri river at Ft. Bellefontaine; the Missouri shore, Chain of Rocks; the 366 Illinois shore, Chain of Rocks; the tap, bacteriological laboratory old city hall, beginning May 8th, ending October 9th, 1900.

We make a comparative estimate beginning with the weekly averages at Grafton from January 23d to 30th, and compare it with each one of these elevations upon this chart for the individual stations where the samples were collected. The result is as follows: (See table "Abstract" and Rec. 366.)

376 This map indicates that the water of the Illinois comes into the Mississippi, so far as can be ascertained from the bacterial contents of the stream taken in the center of the river, we show a mixture both at Alton and at Hartford.

This is also a comparative estimate of the waters, of the cross section of the stream, Missouri shore, intake, Illinois shore, as you see here, show that quite often there is an intimate mixture at the intake of the waters of the three rivers, that is bacteriologically as is indicated on the two sides of the intake.

The waters of the Mississippi river and the Missouri river commingle at the intake, at times they do markedly, that is estimating the number of bacteria.

377 From memory I remember that the Illinois river was high from February 12, to 20, 1900. I know that the Mississippi river was covered with ice at the time and it was low, comparatively speaking. I know that the Missouri river was covered with ice at the time, and was comparatively low. In fact I know the period of the thaw in the whole Illinois river valley, the river was swept out, in February, 1900.

Beginning in the middle of February and running for a couple of months, all the rivers were high. They had the spring freshets then. That is when the bacteria flows in such enormous numbers, in all rivers.

378 The flushing of streams by the rains and floods increases the number of bacteria in the channels of the rivers.

In the Missouri river there are generally two periods of rise, there is the spring rise, which occurs as soon as the thaws and rains of spring begin, which may be in February or it may not begin until the latter part of March, depending on the weather. Then there is the flooding of the river with the thawing of the ice on the mountains, which generally is in June. The flood tides of the Mississippi are highest in spring. If there should be heavy rains in June there would also be a rise then.

I know that when the Mississippi and Missouri are high, the Mississippi river above the mouth of the intake is high, the flood volume, I don't know at this time from memory.

It shows on this chart, (chart not identified) for the Illinois river, for the week beginning February 13, there
379 was a very high rise in the Illinois river which extends to
the week beginning March 27.

During that period of time that bacteriological examination discloses to me as a bacteriologist that the water from the Illinois and Mississippi rivers was coming into the intake tower.

Here is the period of time at which the Illinois river was flushed. I call attention especially to the dates beginning in the week of February 13, and say extending to the week beginning February 20, during which time the numbers of bacteria in the Illinois river at Grafton were 257,600 and 221,800 respectively, for those two weeks.

The Mississippi river at that time was covered with ice, and the river fairly high. For the week beginning February 6, the number of bacteria in the Mississippi river at Grafton was 46,000, and the week ending February 13, the number of bacteria was 161,000. For the week February 20, at Grafton, Mississippi river, it was 105,500.

For comparison of weekly averages which witness claims shows an increase of bacteria in the Illinois as compared with the Mississippi and the commingling of those waters, see
Rec. 379.

380 I am giving the bacteria per cubic centimeter for weekly
averages, taking a definite period of time, and I show you by the river stages that the Illinois river was high at this particular time and contained enormous numbers of bacteria; that these other rivers were covered with ice, and were low in bacteria.

This chart shows that a mixture of the Illinois and Mississippi river at Hartford, and the mixture of the Mississippi river and the Illinois river and the Missouri river at the intake

That is on the quantitative determination of the numbers of bacteria.

381 This chart, (Exhibit No. 2) is marked "Results showing mixture of the waters of the Mississippi and Missouri rivers at the Intake of the St. Louis water works, bacteria per cubic centimeter for the weekly estimations.

The bacteria per cubic centimeter on the Illinois shore is marked in black; the intake tower is marked red and the Missouri shore is marked blue. The figures on the left hand column indicate the bacteria per cubic centimeter.

The weekly estimates are here marked in black, upon the dates named, in the lower margin of the chart giving January 23, 1900, and extending through until October 2.

(The determination of whether the waters commingle at the Intake and what waters predominate is effected by taking the number of bacteria at the Missouri shore, the number at the Illinois shore and noting how the number at the Intake compare therewith.)

382 Complainant's Exhibit 3 is a chart of the weekly average of the result of quantitative determination of the number of bacteria in samples of water collected daily from the Mississippi river at Grafton, two miles above the town, together with the stages of the river at Missouri shore.

The red indicates the bacteria per cubic centimeter, and the blue represent the stages of the river.

On the left hand side we have the number of bacteria
383 per cubic centimeter, in five thousands, running from
zero up to 250,000. Next to that we have a column bearing the stages of the river in feet running from zero to 25 feet.

My assistant, Mr. Johnson, made this chart, at my direction. This is also true of the chart marked complainant's Exhibit 2.

384 This shows that as a rule, running through here when the river is falling, the number of bacteria decreases

markedly; when the river is rising the number of bacteria run up to great heights.

This table shows that when a river steadies itself and is not washing the surface soil a great many bacteria disappear, not by settling but they are washed into the stream, it simply holds itself steadily, which shows here right straight along.

385 (Complainant's Exhibit 4.) This chart shows a weekly average of the results of quantitative determination of the number of bacteria in samples of water collected daily from the Mississippi river one mile above Alton, Illinois, together with the height of the Mississippi river at Alton, Illinois.

The chart was made from the data collected during the period January 23 to October 9, 1900, under my supervision. The determinations were made in the bacteriological laboratory at the old city hall, and medical department of the Washington University. These figures of stages of the river were obtained from the government meteorological survey. The bacteria per cubic centimeter is arranged perpendicularly, on the left hand margin of the page, beginning at zero and running to 250,000. The figures in relation to the bacteria per cubic centimeter are perpedicular and marked in red. Next to that, in blue, are the stages of the river running from zero to 25 feet.

386 When the river is high the number of bacteria is high. The greatest height of the river is reached on March 13, when it was 16 feet and about 4-10, and the number of bacteria recorded for that week is 312,000 per cubic centimeter.

388 (Complainant's Exhibit 5.) Chart same as above for Mississippi river at Hartford, Illinois.

389 Q. Now what, if anything does the bacteriological examination as disclosed by that chart, show with reference to the rise of the waters of the river and the fall of the waters, and the increase or the decrease in the number of bacteria per cubic centimeter, in the water bacteriologically examined?

A. With the rise of the river we find an increased number of bacteria in the water, and with the fall of the river, as a rule we find a decrease in the number of bacteria; so rising and falling then, as the river rises, beginning at its lowest period, it rises steadily until February 20, when the height of 7.9 feet is recorded; the number of bacteria at that time being 266,700. The river then drops to 5.6 feet in the week beginning February 27, when the number of bacteria dropped to 193,000 or 194,000, and then the river rises rapidly, in great volume, until the week of March 13, when 320,500 bacteria are recorded, as the weekly average; then with the fall of the river the bacteria drop very rapidly. The river falls in the week beginning April 27, to 2.2 feet about. The bacteria in that week fall to 60,000. The river seems to hold itself steadily here, falling until July 10, then there is a slight rise, the bacteria holding themselves steadily in the meanwhile, fluctuating between 7000 and about 2000.

390 (Complainant's Exhibit 6.) Same as above showing same condition at Ft. Bellefontaine, on the Missouri river.

393 (Complainant's Exhibit 7.) Chart showing same conditions at Chain of Rocks, Missouri shore.

395 The rise of rivers is caused by either thawage of snow and ice, upon the drainage area of the river, or rainfall upon it. This means water rushing towards the lowest part of the drainage area, sweeping the surface of the soil of its bacteria and carrying them with the water and debris into the river, and when the river falls and no longer has the bacteria swept into it from the surface washings, the river depends upon springs and sewers for water. That is, these particular rivers. Spring water is a good water and contains very few bacteria, consequently the numbers of bacteria during the falling or low stages of the river, are small.

397 (Complainant's Exhibit 8.) Chart representing same conditions at Illinois shore, Chain of Rocks.

400 (Complainant's Exhibit 9.) Same, Intake Tower, Chain of Rocks.

404 (Complainant's Exhibit 10.) Same chart for Illinois river three miles above Grafton, Illinois, without the height of the river recorded, the height of the water to be filled in later.

406 Prior to 1895 the Intake Tower of the St. Louis water works was located 3½ miles from Market st., measuring by the river, up the Mississippi, at a place called Bissell's Point.

It was not near so well built as the present intake. It was built a short distance from the shore connecting with a bridge. It is an iron tower into which the water flower and was carried by low service pumps to reservoirs that were located at this point. When the river was very low they had a movable intake that ran down a tramway, carrying a flexible tube to follow the river out. The water was pumped directly from the river instead of running into the intake. There was a creek about 1,000 feet above the intake at Bissell's Point, known as Harlem Creek which discharged itself into the Mississippi river. This has a drainage area upon which there resided at that time probably 10,000 people. The sewage from these 10,000 people discharged upon this drainage area and into this creek, also the offal from a number of dairy stables that were built out and projected over this creek. All of this material during freshets was washed into the Mississippi river and at times flowed directly into this Intake at Bissel's Point.

407 This Intake was there 25 years ago. The city stopped pumping from the river at that point and began taking water from the Intake tower at Chain of Rocks in 1895.

408 I know that in 1892 the sewage ran into the Mississippi river about 100 feet above the intake at Bissell's Point, because I saw it doing it.

I know in '92 the attention of the Health Commissioner was called to this thing of the typhoid epidemic having resulted from this Harlem Creek discharging the sewage into the intake and a dam was thrown across Harlem Creek and pumps used so that the water that came into Harlem Creek was stopped and pumped across, and discharged below the intake of the water workes, into the Mississippi river.

The typhoid epidemic following the discharge of this sewage occurred the latter part of August, 1892, and extended until February, 1893.

I made a personal investigation and found that standing on the bridge out on the Intake tower at Bissell's Point, the black dirty water from Harlem Creek could be seen running along in the yellow water of the Mississippi anl entering the Intake tower of the St. Louis water works. My atten-
410 tion was called to this in October, 1892. Dr. Francis, the Health Commissioner, and the St. Louis Medical Society made an examination. The facts were reported back to the Health Commissioner and he attempted to turn the course of Harlem Creek, over 500 yards back from the river. Pumps were established and the water pumped from this Harlem Creek to a point below the intake of the water works. That was practically the end of the typhoid fever there.

From the chief sanitary report of the Health Department for the fiscal year ending April 1, 1893, 3,624 cases of typhoid were reported to the health authorities by the officers of the city, with a total of 514 deaths.

The figures for the preceding year I obtain from the annual report of the Health Department of St. Louis. They are monthly and will be found on page 624 and 625. A great majority of the cases, 3,385 with 442 deaths, occurred during the months of September, October, November and December, 1892, and January, 1893.

412 I examined the Mississippi tap waters from the tap in the bacteriological laboratory and succeeded in separating out a micro-organism that resembled a stock culture very closely stock culture of bacillus typhoid. I thought it was the typhoid bacillus at the time and I still think so.

This was taken from the tap during this epidemic of typhoid, on November 8th. I did not make any bacteriological examination of the waters of the creek as it was crude sewage and the numbers would be up into the hundreds of thousands, so I did not plate it.

413 I examined the conditions along the banks of the creek. All along from probably 400 yards from the mouth up to quite a distance along the crek are a number of dairies with their cow sheds projecting over this creek, and the manure is pitched out through the holes in the floor into this creek, great masses of it, lying there fermenting, and it is there still. I was over there the other day and saw it. A part of this drainage district extends into Bellefontaine cemetery and the other part is a rolling upland, and is inhabited and the sewage from all the people on this drainage area, probably 10,000, discharge into this creek, so that in dry weather the flow of this small creek has black fetid water flowing in it.

Prior to the breaking out of the epidemic there was typhoid on that drainage, of which there is a record in the health department.

414 In 1892 there was no other source of supply except that from Bissell's Point, with the exception of 7,000 wells scattered throughout the city. A mass of the wells were inspected and it was found that the typhoid fevers were uniformly distributed throughout the city and not around any particular well or wells—distributed independently of any well water.

In my investigation of the matter at that time I did not discover any cases among the families that used well water. The water was pumped directly from the river into the settling basins there, but the demand for water was so great in the city at that time that it rested but a short time; it was practically water delivered from the river to the consumer.

415 Describes method of examination of water at that time. Sound bacteria. It responded to all the tests and was declared by me to be typhoid bacilli.

417 This particular micro-organism lived in sterilized tap water, in an ice chest, right up against the ice, from 30

to 60 days. In non-steriled tap water in the sunlight they lived from 12 to 15 days, and in the gloom or dark of that ice chest, 24 to 30 days.

The chart here shown shows the number of cases of typhoid fever and the number of deaths in St. Louis from 1890 to 1900, graphically. I made that map. Besides that it graphically represents in groups the weekly averages of the river stages at St. Louis, the Mississippi river. The map goes further and shows another period which we will describe later. It was made from the official statistics of the St. Louis Health Department.

418 From 1890 to the year 1895 the water supply was taken from the Mississippi river at Bissell's Point. At the present time it is taken from the Intake tower, Chair of Rocks.

On the left hand margin of this map are written figures beginning with zero and running up to 200, written in black ink and they represent the cases and deaths, from typhoid fever. In the second column, or third from the left hand margin, the stages of the river, in feet, taken from the government figures and represent the stage of the river at the foot of Market

419 st., in St. Louis. The curved line in blue indicates the stage of the river. It begins in January, 1900, and the stage of the river was 6.1.

The black lines indicate the number of cases of typhoid fever reported to the Health Department and the red lines indicate the deaths from typhoid fever.

Witness reads from chart, beginning on page 49.

432 We find, in consultation with this map, that as a rule when the river is low the typhoid fevers were high, the number of cases and deaths. I mean the water low in the river.

On this chart is a separate chart running to December, 1900, upon which is shown the curves showing the weekly average of the stage of the Mississippi river at St. Louis; percentage of Mississippi water taken in; total solids flowing into the Intake, and number of typhoid fever cases for the year 1900.

I mean by total solids the residue remaining after evaporation. I made this map—it was under my direction. The data of the typhoid cases taken from the Health Department;
433 the total solids were taken from the figures of Dr. Wm. C. Teichmann, city chemist. The river stages were taken from the government reports.

434 Witness reads percentages shown on small map.

439 This map shows that typhoid was most prevalent in 1892. Prior to 1900 typhoid was most prevalent in the fall and winter months.

After a person receives the typhoid bacillus into his stomach the disease will develop itself from five to six days to three or four weeks.

440 Q. Now is there any relationship as shown by this map between the rise in the number of cases of typhoid fever and the rise in the percentage at the times you mention of the water in the Mississippi river at the Intake tower?

A. Yes, sir.

Q. Just explain what that is.

A. As I showed you already, on the 18th, 100% of the Mississippi river water, as it came into the Intake tower of the St. Louis water works—

Q. What do you mean when you say 100 per cent?

A. 100% of Mississippi river water. In other words the Mississippi river water only—not mixed with the Missouri river water, went into the Intake tower and on March 3d, there was an increase in the typhoid cases. That is February 8th and March 3d and 23 days later a rise in the typhoid death rate was noted and that increased until March 17th, gradually decreasing with the falling out of the Mississippi water here. The Mississippi water reached 12 per cent on the 17th of February,
441 and the typhoid fever cases on April 21st were recorded only 4. So that there was an increase of the typhoid cases from March 3d up to March 17th, then a gradual decrease to March 24 and from March 31st to April 7th, and as I say, reached the low number of four on the 21st.

From January 27 to February 10, the Mississippi river was falling, in 1900, and the Missouri river also at those dates was falling. I know that from February 6th, I think it is, to February 20th, the Illinois river was high.

The Mississippi and Missouri were frozen over from February 3d to February 20th. I think about the 20th they broke up.

Q. What effect on the oxidation by bacteria or organic matter, and animal and inorganic matter, in the water, does the freezing over of the river have?

A. The bacteria do not multiply very rapidly in cold water; they remain dormant.

Q. Well, the oxygen is shut out of the water by the freezing of the ice?

A. Yes, but there is enough oxygen in the water for the bacteria, if they could multiply in the temperature, but not so much as when the river is open. The organic matter in the water is not decomposed in so great a quantity.

Q. If there was organic animal matter in the water of the Mississippi river and in the Missouri at this time, its decomposition would be the result, if it was open and not frozen?

A. Yes, and the temperature higher, and the temperature not near freezing point.

442 Witness reads stages of Illinois river at Peoria from January 17 on.

444 These figures show that from the 23d day of January or from the 17th of January there was a steady rise in the Illinois river until the 29th of January, when eight feet were recorded, then there was a fall to 7.9 feet, and 7.8 feet on February 1st. It rose through February, March and April. 19.9 feet was reached on the 17th of March, and that is the highest.

Q. Do you know the date the Illinois river broke up?

A. Well, from what I understand, there was a thaw along the Illinois river beginning the 7th of February and it extended to April 12th. The river I see here begins to rise on the 8th, and rises steadily from the 8th of February, and from the bacteriological record, and from personal recollection of samples collected at Peoria, at Joliet and Grafton, I know the condition of that water.

445 Trace the relationship there between the percentage of of the Mississippi river water as shown by this map and the increase or decrease of the typhoid fever rate.

A. We have traced that increase from March. That is for February, and the increase of typhoid fever that occurred in March in St. Louis, and no such thing has ever been known before in the history of this town; the Illinois river high, and the other two rivers covered with ice, and the Mississippi water coming into the intake in 100 per cent. Now as the rains began and the spring thaw began on the drainage area of all these rivers in the latter part of February and in March, there was high water for all these rivers, so the flood flowing into the Mississippi river was very great. From the 17th of February on, we find the highest stage of the Mississippi reached at this point was on March 17, 1900, and the highest stage also recorded for the Missouri at this period. This stage for the Mississippi was 22.4 feet and for the Missouri river 16.2 feet. Then the rivers fell until March 31, when again there was a rise. Then a gradual fall until the fall rise, which began on September 29th. Now at this time, according to the total solids, that is, beginning on March 3d, and reaching its acme on March 24th, we find that on March 24, 25, 26, 27 and 28th there was 100 per cent of the Mississippi river water going into the intake at St. Louis water works, Chain of Rocks. Then there was a fall to 62 per cent on the 29th of March; again a rise on the 31st to 100% ; then a fall to 87% on the 1st of April and on the 2d of April to 50%. Then a rise on the 3rd of April to 62%, and a fall to 56% on the 5th. And on the 6th to 32%, and then, on April 7th to 1 % ; then again it rapidly rose.

446 Q. Now what was the number of typhoid cases?

A. At flood volume of the river. It was very high at this time and the number of typhoid cases rapidly diminished. All the rivers were very high, and the quantity of the pollution was very great. And the percentage of the Mississippi river water at the intake was high at one period, at the very high period.

Q. It wasn't high when all the rivers were at flood tide?

A. Yes, it was high once. That is the period I have just referred to from March 24th to 31st. It was 100%. I named the dates. It reached 100% twice in the spring and fall of 1900. So the quantity rises and falls; that is, the percentage of the Mississippi river water at the intake rises and falls until May 28th, when it is at its lowest; then it remained low, that is, rising and falling to a slight degree until July 29th, when it again rose, and the amount of Mississippi river water going into the intake reached 39 per cent. I can read farther on if you care to have me.

Q. Well, just trace the relationship there is in it between the typhoid rate and the percentage of the Mississippi river water.

A. The waters during this stage now, are—the Mississippi at the intake is falling when its percentage reaches 39; then the percentage fluctuates between the dates July 29th to August 7th, when it reaches 6 per cent. On August 31st the percentage again reaches 50 per cent. It falls on August 2nd to 2 per cent; then rises again to 28 per cent until the 5th of September. On the 7th of September it falls to 4 per cent, then it rapidly rises to the 12th, when it reaches 40 per cent.

447 The number of typhoid cases at that time was increasing, with the increase of the Mississippi river water at the intake at this low stage of the river.

The number at that particular point was forty cases. The percentage now fluctuates between 26 per cent on the 15th of September to 46 per cent on September 22nd; then there is a fall again, September 25th, to 34 per cent; then a steady rise until the percentage of 64 per cent is reached on October 4th.

Then it falls on October 6th to 27 per cent. rises on the 7th, October 7th, to 42 per cent· falls on October 9th to 24 per cent; on October 10th to 26 per cent, and the record ends there. When the flood volume of the river is very great the percentage of typhoid is very low.

Q. What water?

A. The percentage of the Mississippi river water at the intake, when the river is high, the typhoid is low. The typhoid fever rate increases with the increased percentage of Mississippi river water going into the intake.

Q. Take all this period here, the latter part or half of 1900, just give us the periods of time—just the dates, that is all, at which the typhoid was the greatest in the city of St. Louis—I just simply want the dates as shown by your map.

A. For the March term, for March 3rd, to March 31, extending into April 7th—March 3rd to April 7th, was one period, and from August 1st to December 15th.

448 I have made a calculation to determine what percentage of increase there was in March, 1900, of the typhoid rate in this city, or with that of the month preceding, February, 1900. It was greater for the period of March. For the period of February there is very little difference. For March there is an increase over March of the previous year. The number of cases of deaths from typhoid reported is as follows:

March, 1900, 40 cases.
March, 1899, 3 cases.
449 March, 1897, 3 cases.
March, 1896, 6 cases.
March, 1895, 6 cases.
March, 1894, 15 cases.
March, 1893, 14 cases.
March, 1892, 5 cases.
March, 1891, 6 cases.
March, 1890, 7 cases.

Above map offered in evidence as complainant's Exhibit No. 10.

When the flood volume of the river is very great the percentage of typhoid is very low—the percentage of the Mississippi river water at the intake and when the river is high, the typhoid is low. The typhoid fever rate increases with the increased percentage of the Mississippi river water going into the intake.

There is an increase of typhoid fever patients for March, 1900, over March 1899. It is greatly increased in March over February. The highest number of typhoid cases was recorded on the 17th of March, 1900, forty cases.

Above map offered in evidence as complainant's Exhibit No. 10.

449 This other map is for the third period, 1901, for the
months of October and November. It shows the results
of the daily determination of the number of bacteria in sam-
ples of water collected from Drainage Canal at Bear Trap
Dam, Lockport, below Ruby street, Joliet, and Bran-
450 don's Bridge, Joliet. The bacteria per cubic centimeter
are ranged along the left hand margin of the map be-
ginning with 200,000 and extending up to 5,000,000 bacteria
per cubic centimeter. The bacteria at Bear Trap Dam, Lock-
port, are marked in black ink; at Ruby street, Joliet, in red;
Brandon's Bridge, Joliet, in green. On the 4th space at the
top of the map are the dates, beginning Sept. 26 and ending
Nov. 29, the number of bacteria are recorded every third day—
not every day.

The greatest number recorded at Bear Trap Dam recorded on this map is 7,200,000 on Nov. 23.

452 Now the water tumbles over the Bear Trap Dam and mixes it with the Des Plaines river and pollutes it somewhat, so that we see the pollution in this graphic representation.

Witness then reads from chart.

453 Now then we have the green line for Brandon's bridge. It shows a mixture of every stream and everything else that comes into the Des Plaines river—a mixture of the Drainage Canal with the Des Plaines river; the I. & M. canal with the Des Plaines river and the sewage of Joliet. The figures are as follows: (See Rec. 453.)

455 This map shows that the number of bacteria was the highest beginning the 17th of November—there was a lapse between the 10th and 17th—beginning on the 17th and up until the 23rd, when they reached the highest, but they are still high on the 25th, at all of these points.

The highest point was the Bear Trap dam.

Map offered in evidence as Complainant's Exhibit 11.

This chart you now show me is the result of daily quantitative determinations of the number of bacteria in samples of water collected at Peoria, Illinois, at Shady Beach, above the city; covering a period of time from Oct. 1st to Nov. 27th.

The lines and figures on this map, beginning on the left hand margin, show the number of bacteria per cubic centimeter, ranging from zero to 10,000, in black. The river stages in feet are printed in red and range from zero to 10 feet. At the top margin of the map are the dates from Oct. 1st to Nov. 30. The figures are as follows: (Rec. 456.)

457 This map shows there was a decided and rapid rise from November 13th to November 17th; then it dropped until Nov. 21, and then a rapid rise on Nov. 23 to 9,000, and then a drop for the 26th to 500. It seems to correspond with the rise and fall of bacteria at Bear Trap dam, Ruby street and Brandon's bridge at Joliet.

458 During this period the stage of the river remained remarkably even throughout, and when the bacteria was so high for the two periods in November, the water was a little bit lower than it had been for previous weeks. (Witness then reads the figures showing stage of the river for period referred to.)

459 You see the river fluctuated an inch or two only. The river remained stationary practically during this period from October 1st to November 29. In any ordinary river the bacteria would have remained practically stationary, but in the dates as given before you find a remarkable rise without any rise in the river.

This indicates that large numbers of bacteria put in above apparently came through to Peoria.

460 Q. Now above the Bear Trap dam, in the Des Plaines river, have you any analyses of that water?

A. Yes, that has already been sumbitted.

Q. Now you have investigated those analyses, have you?

A. Yes.

Q. What does it show—a larger or smaller number of bacteria above the Bear Trap dam than it does below?

A. Oh, a very small number, comparatively.

There is no other place than the Chicago canal at the Bear Trap dam from whence this large number could come into this river at this stage of the water.

I have the rain precipitation in that tributary of that river for that period. There was no precipitation practically in that area at that time.

Map introduced in evidence and marked Complainant's Exhibit 12.

Q. What is this map I show you?

A. This map is made up from results of the daily quantitative determination of the number of bacteria in samples of water collected from the Illinois river at Grafton, Illinois, from Oct. 1st to Nov. 27th, 1901. The distance from

461 Peoria to Grafton is 63 miles, and the mean fall of the river is thirteen feet.

Description of chart is same as previous exhibit.

Greatest number of bacteria per cubic centimeter were found 17th of Nov., 1901. There was slight rise of the stage of the river at that date, but it was not as high as it had been at a previous period.

462 The river was five-tenths of a foot lower when the greatest number of bacteria was found.

Map offered in evidence as Complainant's Exhibit 13.

I was at Lausen, Switzerland, about 15 miles from Basle, as a sanitary and hygienic expert, in 1897. The town 463 is in the mountains—in the valley. Experiments were made by Dr. Haegler, after the typhoid epidemic of 464 1872, to discover the cause thereof. I have asked him what he knows of the history of this epidemic at this place, for the purpose of showing the manner in which it has been demonstrated that the typhoid bacillus will travel. 465 It went through the mountain, about a mile, and affected the spring at its base, and this mountain acted as a filter sufficiently good to keep out the starchy particles of flour thrown in a mile above, but allowed salt and typhoid bacilli to go through. This spring is enclosed; the spring is in an enclosed space, not open at all.

Never been to Plymouth, Pa., but am acquainted with the literature on the subject and the report made by the Pennsylvania State Board of Health, as to the typhoid fever epidemic that occurred there in 1885, due to the discharges of a 466 typhoid fever patient thrown upon the bank of the reservord that was the source of the water supply of this town. The town had a population of 8,000 and there were 1,104 cases.

Am acquainted with the investigations made—that is the reports of the State Board of Health of Massachusetts and of Dr. Sedgwick's writings of his investigation at Lowell, Lawrence and Newburyport on the Merrimac river, Mass., in 1891-2-3.

Objection by Attorney General Hamlin.

467 The epidemic at these places was due, at least ascribed ot the dejecta from typhoid fever patients getting into

the water supply and being taken and being drank by these people. The town got its water from the Merrimac river.

I think Dr. Sedgwick carried out some experiments to determine the question as to whether or not it was in the Merrimac river, (the bacilli), but I am not sure about that.

Typhoid fever is more prevalent in the fall and early winter, as a rule. The faster water flows the further it will carry bacteria. In waters that flow very slowly, or are stagnant, or still, the bacteria are precipitated into the silt or slush at the bottom of the river. The speed of the river or the volume of the water does not destroy typhoid bacilli.

468 There is a difference in the conditions surrounding the typhoid bacillus in sterilized water in a bottle and the ordinary tap water in the city. Water that has been sterilized by heat contains the inorganic matter of the water, but the bacteria have been destroyed in it. It still has food for bacteria and it has no other bacteria. Now the typhoid bacilli put into that water have no other form organic leife to contend with and the bacteria will live a great deal longer in sterilized water of a district than they do in the living water of that district, in a bottle. They live sixty days.

469 Witness reads from table showing longevity of bacteria at various points along the various rivers, in sterilized waters. Witness then explains manner of collecting and preparing water in which to determine the length of life of typhoid bacillus, and reads on page 722 the weather conditions on each day.

473 Explains the manufacture of the media in which the typhoid cultures were made.

474 The typhoid cultures used in these experiments were: 1, from Dr. Westbrook, of the University of Minnesota, said to have been found by him in the waters of the Mississippi
475 at Minneapolis; No. 2, from a spleen sent in by Dr. W. C. G. Kirschner, from a patient dead of typhoid fever at the city hospital, and plated.

Water was taken from various points set out in the table and innoculated with the typhoid bacillus and they lived under conditions and for the length of time specified in the table, from which witness quoted on page 475.

479 The chances for life of a typhoid bacilli in running river water would be greater than if confined in a flask.

I don't see that the food supply cuts any figure in these experiments. I find that in sterilized, distilled water, micro organisms live for a long time. There is no assertion here made that the typhus bacillus lives and multiplies in the water. It simply lies dormant until its life history is over, unless in the meanwhile it reaches a favorable condition.

The death of the typhoid bacillus in water in a bottle is due to toxins produced by bacteriological conditions that exist there. In running water it lives out its period and dies after a time. Its period of longevity is not definitely known
480 in running water. The distance they would be carried, according to what men know of the longevity now, would depend entirely on the rapidity of the flow of the stream.

In the floodtide of the Illinois and Mississippi rivers, if typhoid bacilli came down from the Chicago river and emptied it in the Illinois river, they would come into the intake tower much more rapidly than they would if the waters were low.

I do not know from my own knewledge anything about how long it takes water to come from the dam at Lockport or from the canal there in Chicago, the Chicago river, down to the city of St. Louis.

481 BENEZETTE WILLIAMS, a witness called in behalf of the complainant, on direct examination by Attorney General Crow, testified as follows:

My occupation is civil engineer and consulting engineer, and I reside in Chicago. Have lived there 30 years. Have been following my profession for 32 years.

I am very familiar with the geography and location of the city of Chicago.

Chicago lies very low. With minor exceptions, elevations of the ground within the city is over the lake level to a height of 25 feet, and a very large portion of the city lying but a few feet above the lake level, both the old and central portion of the city and other portions, so that the process has been in the settled parts of the city, to raise the grades in order to get the depth to cover their sewers, and to get sufficiently out of the mire, you might say.

In other portions of the city they are overcoming that difficulty now by building sewer districts; building the sewers in districts and pumping the sewerage. They build sewers below the lake level and pump a flow to the lake level or to a point of discharge.

482 The soil on which the city is built is reasonably firm.

The greater portion of the city of Chicago is clay soil, overlaid, of course, with prairie soil originally, which is a soft loamy soil, free of stone and gravel. You find stone in the underlying clay. It has a glacial portion. Clay has what we term a glacial portion, and it is more or less filled with stone; that is sometimes cobble stone size and a gravel material to a greater or less extent. In some places you will find this clay quite pure with very little of that with it. In other places you will find almost a complete mass of boulders cemented together with clay; then another portion of the city lying directly along the lake at a certain depth consists of this same clay, but it is overlaid with a sand ridge formed by the flowing up of the lake and the washing and blowing of the same into the ridges. That is close to the lake, however.

But a small proportion of the surface of the city limits is on the lake level, but there are a great many square miles that are so low that you have to pump in order to get drainage. The land is flat, apparently, in its natural condition. It would seem like a dead level with the few exceptions of these sand ridges.

483 The greater portion of it would be about 12 and 14 feet above the low water of the lake, what you call Chicago datum.

The Chicago river and in fact all of the rivers that empty into the lake along the southern and western portions of Lake Michigan, you may say, have been formed as the lake shore—as the water receded, and the lake shore was built up so that they have been formed, so that they run parallel with the lake. They have been shut out from the lake as the waters receded by ridges of sand or drift, or something that has come in and left them running parallel with the lake. That is a peculiarity of that portion of Lake Michigan.

The Chicago river is short, originally not over a mile long from the lake back to the confluence of the two forks; one leading from the south and one from the north; the southern fork called the south branch and the northern fork called the north branch. The northern branch really drains the most territory and from a district of higher elevation somewhat as its source, which is in the State of Wisconsin. The south branch at a distance of about 5 miles from the lake, as it originally existed, has two branches, one known as the west fork, and the other as the south fork. The south fork draining a very limited territory, wasn't much, you could hardly call it a stream except in floods. The west fork only drained a small territory also, except as the flood waters of the Des Plaines river at a distance of about 9 or 10 miles from the lake would break over and come down
484 the west fork of the river; then that would become a large stream.

The Des Plaines river is another stream running parallel with the lake, but it is more remote from the lake.

The upper Des Plaines river heads in Wisconsin and flows southward until it comes to South Chicago, and about ten miles distant from the lake, when it turns southwest and joins the Kankakee, below Joliet, forming the Illinois river.

There is a divide between the Des Plaines and the south branch of the Chicago river. That is the Des Plaines never flows into the Chicago river except at one point where it turns southwest to the Illinois river. It has always within recent geological times, at high stages, flowed both ways. It would divide, one portion going to the southwest, the other portion going to the east and through the Chicago river to the lake.

The distance to the extremity of the west fork of the Chicago river, of the south branch of the Chicago river, was only a very few miles, and really, within thirty years you may say it has been practically connected with the Des Plaines river. They built out there a ditch—the land owners did, and absolutely tapped the Des Plaines river and drew it to Chicago, even at low water, until the city went and built a dam and shut that off and restored the natural condition.

485 That is outside of the city limits and the distance from the present city limits is about 3 1-2 miles.

The north branch takes its origin at a distance of about 20 or 25 miles.

In the ordinary stage it is not a large river and in extremely dry weather it disappears practically. We have had floods there that discharged about 210 feet a minute—cubic feet in the north branch.

The mouth is a harbor now—it has been dredged and docked. The stream has been widened and deepened, by dredging.

486 Where it has been dredged it varies from a rapid current in high stages to no perceptible current at all. In ordinary times it is modified by some artificial work that has been done by the city, pumping works connected with it. The pumping works are at Fullerton avenue. There is a conduit extending from the lake to the north branch on Fullerton avenue, twelve feet in diameter, and a pumping works connected therewith. The works are at the river, but the conduit is below the lake so that it acts the same as if it was at the lake. It merely takes the water from the conduit and throws it into the river.

487 The capacity of the pumps when at its usual working capacity, is 15,000 cubic feet a minute. That was built about 1879. The conduit strikes the lake on the shore through Lincoln Park—it strikes the north shore of the city. It is adjacent to a densely populated portion of the city and extends directly west from the lake to the river 12,000 feet.

That conduit is in operation with the pumping works now at intervals, sometimes it is not working. The effect of that is to flush the river out to a greater or less extent, depending upon the amount of water put in. When flushed out it emptied at the confluence of the south and west branch of the river and from thence into Lake Michigan except as it went down the south branch due to a change of the regimen of the river.

488 For thirty years, there has been a flow through the south branch, southwest to the Illinois and Michigan canal.

The north branch carries the most water in its natural stage, except as I say in the Des Plaines river flood. As far as the size goes, in the rivers, as they stand today, perhaps there isn't much difference; they have been docked and dredged to the same depth and width.

From the confluence of the south branch and the north branch of the river to the exit in Lake Michigan, as it exists today, with the piers that have been extended out into the lake and caused a channel, is, I think about 7,400 feet. It is exactly 7,113 feet.

489 I can not say exactly how far the present opening has been extended out into the lake by artificial means. Nearly half of that distance is an extension from the original. There has been a filling in of the lake front at the mouth of the Chicago river with soil, debris, etc.

The mouth of the Chicago river was at one time, nearly half a mile south of where it is now. It turned south. It didn't change the river where it was naturally, you may say, from Rush street to the confluence of the forks, and at that point it turned south and entered the lake nearly half a mile south of where it is now. There was a bar existing there at what is now the outlet. They cut through that and have filled that old channel of the river—south of the river, what was the old channel of the river, and they have been filling continuously more or less, and are today, out into the lake. I think the north branch is dredged and docked about four miles from the conjunction of the main river, but it is being dredged up as far as Lawrence avenue, about six miles above the confluence of the two branches of the Chicago river.

As far as it is dredged and docked at the present time it is opened for shipping and used for that purpose. The
490 depth is very near fifteen feet. Sixteen feet has been about teh deepest they have dredged up to within a few years.

The City of Chicago has been building a conduit at Lawrence avenue for several years, but there has been difficulty with the contractor and it is now tied up. It is 16 feet circular inside and will connect with the lake and extend across to the north branch of the river similar to the manner of the Fullerton avenue conduit and is in the northern portion of the city of Chicago.

That conduit is to take away by means of a system of intercepting sewers the sewage that now discharges into the lake along the north shore over to the north branch of the Chicago river, and it is also to take the supply of water from the lake to the north branch, with the view of emptying that sewage into it by means of the pumping station into the north branch of
491 the Chicago river which now goes into Lake Michigan.

The west fork of the south branch of the river has its origin very near to Ashland avenue and 31st street—or Ashland avenue and 26th street, in the limits of Chicago. It flows only one way; to the east, slightly to the north and flows in that direction now.

The volume of water is less in that than in the north branch, for ordinary times, but more at other times. That is there have been especially in the past before there were any changes in the conditions of the river, flood waters of the Des Plaines which have overflowed into that river, and swelled that river to a greater volume than the north branch.

Aside from any artificial interference the west fork carries more water than the north fork at high floods of the Des Plaines. Where the Des Plaines overflows, breaks over and connects with it. That happens now but to a somewhat reduced extent. A flood must now be higher than in the past in order to furnish the supply to the north branch, but in very high floods it still furnishes a large amount of water there.

492 There is very little, almost no speed in the current—an almost imperceptible flow. It is dredged and docked for a considerable distance about the confluence of the south branch of the west fork, I should say two miles more or less. From the confluence of the two large branches of the south fork of the Chicago river to what was formerly the mouth of the Chicago river at Lake Michigan is about five miles.

The origin proper of the south fork of the south branch of the Chicago river is three miles south of its confluence with the south branch, and it was, you might say, merely gullies leading into a larger channel—it ran out into the prairies—it was practically no river at all, connected with what is known as the west fork. The drainage area of it was originally prairie with a flat surface and in the ordinary stage there was no water
493 in it—it was only a storm water drain.

At this time the south fork of the south branch is dredged and docked to the stock yards and that is one and one-half miles from the point of confluence of the west and south forks of the south branch of the Chicago river. It is dredged and docked for shipping. It is about 14 feet deep; lake vessels can pass in it there to the stock yards—they did do it. By the stock yards I mean the principal stock yards of the city of Chicago and the slaughter houses and packing plants.

All the live stock that goes to Chicago, except perhaps some that goes to Hammond, Indiana, goes in there.

There has been a conduit built from that we call the east arm of the south fork; that arm is merely a slip dredged
494 out for docks, for ships; the conduit leads to the lake and is 20 feet in diameter. It is to be used to carry sewage from the district, from Lake Michiagn on the south shore,

and south side, to the stock yards slip, and to take the sewage in from the lake to the stock yards. It is to be taken in for the purpose of supplying water to the river and flushing that south fork, that is, purifying it, putting in better and making it better in a sanitary way, and of furnishing water to the drainage canal. Pumps are being built there for a capacity of 120,000 cubic feet a minute. The main conduit is finished, they are cleaning it out now. The pumps have not been built. No one knows exactly when it is proposed to open that; probably in the course of a year.

495 The length of the conduit is 12,000 feet. There has been dredging going on in the channel of the south fork of the south branch of the river recently, especially up to te hmouth of this conduit, or the outlet of this conduit that is to be. Within the past year. They are certainly deepening it. They must have deepened it in the neighborhood of twenty feet. They are deepening at least at the outlet of this conduit, to the bottom of the conduit, which would be over twenty feet.

There is no flow in the south fork of the south branch except as comes from the sewage discharged into it and from the various sewers that connect with it.

496 The area of the sanitary district of Chicago is 185 square miles. After the legislation establishing the Sanitary District Board, I was chief engineer of the work from January, 1892 to some time in 1893, about a year and a half.

That area remains the same now as when established.

497 The sanitary district of Chicago is bounded on the north by Devon street, partly in and partly on the borders of the city limits. (Describes the boundaries of the district.)

498 Out of 186 square miles of area in the district, 141.8 square miles is within the city limits of the City of Chicago and 43.2 lies outside.

The Indiana state line runs north and south at right angles to the southern boundary of the sanitary district.

The eastern limit of the southern part of the City of Chicago joins the State of Indiana; the western boundary of the State of Indiana.

500 Was city engineer of Chicago in 1878 or 1879.

501 Now what would you say as to whether or not the City of Chicago from its topographical and geographical location, is naturally adapted to the easy disposition of its sewage.

Objected to.

The building of the sewers was not a complicated problem in its original inception except in the matter of grades to give to the sewers. Finally a system of grades was established and used that was what might be called unprecedently low, that is the inclination was very slight—that wasn't the difficult thing only it was somewhat of a doubtful thing, that's all. That was caused by the level surface of the ground on which Chicago was built and the long distance you had to traverse with the sewers. In its natural condition water would flood it and stay flooded a good while, but you could and did adapt or fix the sewers to a natural slope to a certain extent. The surface was practically prairie soil and is not a good drainage, of course not for
502 a long distance run. You had frequent connections with the sewers to take off the surface water promptly. The precipitation of rain could not be drained fast enough by natural conditions.

In consequence of that frequent connections had to be made with the sewer to take care of the rain precipitation.

There is a difference in a city with reference to the amount of sewage matter produced according to the population and generally depending upon the manufacturing conditions. And also as to the general custom of connection of the sewers. An iron foundry and a machine shop or a planing mill wouldn't greatly affect the system of sewage, of the quality of sewage, but slaughter houses and stock yards and cattle pens are very liable to affect it materially and do.

In some cities that have a system of sewers the people will not all connect unless they are forced by some board of health. In the City of Chicago, I suppose, practically all connect with the sewer as soon as one is built in the street. It is not a good place for cess-pools because of the impervious clay—that there would not be much percolation from a cess-pool. The sewage would accumulate and overflow. For that reason the sewer connection in the city of Chicago is very large and general. You might say practically that the only population in the city of Chicago that has not sewage connections in their houses, are districts that have not got main sewers built, and those are of minor importance.

504 As compared with my knowledge of the sewage systems of other cities, I think the proportion of organic matter flowing out through the sewers is greater in Chicago in proportion to the population than is usual, and only very extraordinary cases would have a greater amount than Chicago.

All the sewage that is laid below the level of Lake Michigan is in the southern district, about 60th street and east of State street. Compared to the whole city it is small, although it is large in itself. Some portions of it are quite densely populated and other portions even that are not sewered are densely populated. There are districts there where they haven't got any sewers at all, with 19,000 people in a district, in these flat, low districts.

In the territory where the sewer is laid below the level of the lake, that has to be pumped up to the water level to dispose of it.

Am familiar with the Illinois and Michigan canal. It 505 runs into the Chicago river and at 26th street at the place where the canal joins the south fork there is a pumping works. I think that canal was built in the '40's.

These pumps were built by Chicago for the purpose of creating a greater flow through the canal for the sanitary benefit of the Chicago river and were maintained by the city and operated until 1900 I think, when they were turned over to the sanitary district board. The sanitary district board has since turned them over to the Illinois and Michigan canal commissioners. They are now maintained for the purpose of keeping up the level in that canal for navigation purposes.

506 The building of the sanitary canal was for the purpose of keeping the sewage in the city of Chicago out of the lake and polluting its water supply and for the purpose of improving the condition of the river and branches.

The outflow—the outflow of the sewers is mostly in the Chicago river and branches, although a portion goes into Lake Michigan and some into the Calumet river. The Calumet is in the southern part of the city, entering the lake about 92d street. It has its origin in Indiana. There are two branches and they both head in Indiana around the end of the lake and they flow
generally westward, turning for a time, one of the
507 branches turning almost eastward, and a little south of
eastward and joining the other branch, and then flowing
northward and slightly eastward.

After striking the city of Chicago it has been dredged and docked, I think, to a width of 200 feet and eighteen or twenty feet in depth—I don't mean all the way—only its mouth. It is a pretty good sized stream. It has been dredged continuously for three miles at least and then it has been done in places so that the river has been navigable for boats of lighter draft clear up to Hammond, Indiana, a distance of nearly 20 miles from its mouth, following the windings.

507 The south branch of the Chicago river varies in width from 150 to 200 feet. At the bridges there is less than 100 feet up to the point of confluence of the west fork and the south fork. The sanitary district has been dredging and docking it and are preparing to widen and dock it so as to increase the flow and they have made it possible to increase the flow in places. But it don't necessarily mean that the flow has been increased though.

508 They are working to get a standard width or a minimum width of 200 feet and a depth of 26 feet to the central portion of the stream and 16 feet at the docks.

Based on the census made by the board of education of Chicago in 1900, there is a population of 70,636 that drains into or is tributary to the Calumet river.

509 I have made a distribution of the population of the city of Chicago according to the points of watercourses to which it is tributary for the whole city, and I have represented that distribution and division of the city into districts on the accompanying map. The boundary of the city, except the lake shore is shown in blue, etc. (See Rec. 509.)

511 The board of education census is over 300,000 more than the Federal census, for the whole city.

512 I have confined my sewer districts within the city of Chicago—within the limits of Chicago. District No. 4 is outside of the sanitary district of Chicago and there is a small part of districts Nos. 11 and 10 that is outside of the sanitary district.

513 Now, outside of the city of Chicago, within the sanitary district is the town of Cicero, lying west, and having a population by the Federal census of 16,310. Also the villages of Lyons, Summit, part of Riverside, and a certain rural territory estimated in all, including Cicero, 18,145 in population in the sanitary district outside of Chicago. This makes the total population of the sanitary district based on the Federal census, 1,639,456. The Federal census of Chicago is 1,698,575.

515 ATTORNEY GENERAL HAMLIN: Now, at this point as you are proceeding along another branch, I move to exclude from the consideration of the Court, all the testimony introduced with relation to the Calumet district or district No. 4 as marked on this map, as that territory is not involved in this suit; this being an action against the Sanitary district and that territory lies outside of the district. I make that objection in behalf of the State of Illinois.

JUDGE SPRINGER: I make that objection in behalf of the Sanitary district.

ATTORNEY GENERAL CROW: I will offer this map in evidence.

ATTORNEY GENERAL HAMLIN: I object to it on the ground that it is not based, as far as the population is concerned, upon a proper basis; that it is based upon the school census and not on the Federal census.

516 Q. Now give me the population there, according to the school census, then according to your reduction to that corresponding with the same area as the Federal census in the sewer districts as you have divided them.

A. The population of Chicago by the school census of 1900 was 2,000,695. That has been distributed through the several sewer districts which I have mentioned, numbered 1 to 11 inclusive, and the population marked on the map, and they are as follows: consolidating certain districts in accordance with the source of water, or rather this point to which they drain. (Witness enumerates population of each district.) I find the population tributary to the main river and the south branch which is carried directly into the drainage canal by the flow from the lake, and is included in districts 1, 8 and 12, about
517 791,677. The population tributary to the lake on the south shore, and which will ultimately be discharged into the south fork through the 31st street conduit in district 2, 175,182. The population that is tributary to the south fork in district No. 5 is 282,655. That tributary to the west fork within the city limits in district 7, is 74,899. In addition to that I would add that a considerable portion of the town of Cicero has been sewered which lies within the sanitary district and that also drains into the west fork. The population tributary to the north branch of the Chicago river and that is included in districts 9 and 10, is 555,789. The population that is tributary to the lake on the north shore, district No. 11, is 28,878.

Now aside from those districts as described there is a district shown on the map there as No. 3 in the south part of the sanitary district with a population of 18,827; that has not yet a system of sewers otherwise, and while there is considerable population there, they have no sewage outlet. There is also district No. 6 with a population of 9,152, which has no considerable amount of sewers—practically no drain at all.

District 4, which is the Calumet district lying in the city of Chicago south of the sanitary district, has a population of 70,636.

ATTORNEY GENERAL HAMLIN: That is objected to and I move to exclude it on the ground that it is not in the Sanitary district, and not relative to the issues in this case.

Summarizing a little further, I would say that there drains into the main river the south branch and the various forks which are tributary to those rivers, a total of 1,705,020 by the school census, and that there drains into the lake on the north shore and the south shore that are ultimately to go to the
518 Lawrence avenue conduit and the 39th street conduit
now in the course of construction, 204,060. After these conduits are put into operation and the sewage intercepted and turned into the river that would have been distributed on the face of this population directly into the main river, the south branch and the drainage canal, 800,829:

Into the south fork, 476,664;

Into the west fork, 74,892;

Into the north branch, 584,664.

And the same quantity into the Calumet river before mentioned, making up the total population of the city in its manner of drainage.

Now to reduce them to the United States census, all those districts except No. 4, I would apply 16 per cent reduction. District 4 comprises wards or parts of wards that were found not to differ materially from the United States census.

Q. Now do you know approximately the amount of population of the Sanitary district that drains into the north branch of the Chicago river in say about up to the first of January, 1900?

A. Five per cent reduction would more than cover it and this would apply to the other branches of the river.

519 By the Federal census about 170,000 people—the sewage represented by 170,000 would drain into Lake Michigan.

520 The establishing of the pumping works at 26th street set the current of the river the other way and reversed the flow of the Chicago river.

520 The various branches of the Chicago river in the Sanitary district and city of Chicago were very badly polluted prior to January, 1900, with sewage and drainage from manufacturing establishments. The pumps at 26th street were inadequate to meet the purpose for which they were erected. I know that from a survey and examination of the whole question officially in 1886 and 1887. The water supply at that time was polluted by this sewage.

521 The city of Chicago from 1886 on up to January, 1900, was taking their water from the lake at various points of intake according to the dates and times. They took it from in front of the city from two to four miles out. I think none less than two miles. There are now five intakes and there were the same number in January, 1900. The most remote one is four miles out in the lake. They are as follows: (Rec. 52.) They are all connected. Of course the supply depends on the pumping works. There is a great number of pumping works in the city and of course from every pumping works it has a certain district that the supply from those works predominates. Some of them are located at the lake front and some of them many miles in the interior. There are no settling basins. The force is entirely supplied by pumps and there is no natural pressure or water tower. There is no system of filtration.

Describes the beginning and location of the drainage canal. (Rec. 524.) The bottom of the channel of the canal at Robey street is minus 24.46 feet, which means that it is below the datum to which all the levels are referred in the city of Chicago, which was low water mark of 1847 of the lake.

Taking a series of years, the lake fluctuates over a range of four or five feet, and over a range of several years taking the series of years up to a few years ago I found that the datum was 1.9 feet lower than the mean level of the lake.

525 Now there comes the maximum rise of the lake which would go three or four feet above datum; and then there come times when it is a foot below datum. In every year there is a period of minimum level and a period of maximum level, the minimum coming almost invariably about January; the maximum some time in the summer, probably August. Then there are daily and hourly fluctuations due to the variations of the wind. Then there are seasonal fluctuations; there are a term of years often over ten years at a time that the lake will be continuously rising, these seasonal fluctuations, that is from August to January, still going on just the same, but the general trend is a rise—then there is the reverse. These are due, doubtless or probably ascribed to the rainfall.

525 Witness describes the canal. (Rec 525.)

529 Witness gives weekly averages of the flow of water in the canal after January 17, 1900. (Rec. 529.)

531 The pumps at the end of the Illinois and Michigan canal are on the south fork about a quarter of a mile south of the south branch of the Chicago river, which is the channel leading to the main drainage channel, and it takes its water from the south fork. The south fork is a very foul, black and malodorous stream and as fast as this water works out of the south fork towards the south branch it is taken in by the pumps going into the Illinois and Michigan canal, hence the preponderance of at least all that comes up to the capacity of the works from the south fork, goes into the Illinois and Michigan canal when they are in operation. That condition exists now. There is a current in the south fork of the south branch of the river but it is not perceptible to the eye. There is a flow due to the sewage and storm water that reaches that branch which flows northward towards the south branch.

532 The drainage from the stockyards all goes into the south fork or the slips of the south fork at the head of the south fork. Generally the pumps of the Illinois and Michigan canal are in operation. They operate those pumps now purely for the

purpose of navigation of the canal, to keep the level of it, astensibly at least that is what it is done for.

With the present flow of water through the Chicago river and the drainage canal the south fork of the Chicago river is yet stagnant water. At this time it is black, absolutely black. The lake water enters the river at its mouth.

533 The current in the north branch of the Chicago river is perceptible at times and at other times it is not. It is affected by storms and by the operation of the Fullerton avenue conduit—it is rather irregular—intermittent.

When the pumps at Fullerton avenue are at work they pump in 15,000 cubic feet a minute which would make a slow velocity in the canal. When they are not at work and when there is no storm water flowing, then it is stagnant.

The Illinois and Michigan canal, the only time I have seen it since the main drainage canal was open, it was apparently like it used to be before that channel was put in operation, very black and odorous and with a flow in the channel. There
534 was a flow prior to January, 1900.

When they are operating the pumps to their rated capacity there is a flow of about a foot in a second. That would be about two-thirds of a mile an hour. The Lawrence avenue system of intercepting sewers consists of an intercepting sewer beginning at the upper end of the sewer at the north line of Lincoln Park, and running northwardly to Lawrence avenue; and another one beginning at the city limits or near the city limits on the extreme north and running southward to Lawrence avenue, and making connection with Lawrence avenue, and on the line of Lawrence avenue to the river and the north branch of the river, those intercepting sewer systems, I would say are built; that is the sewers I have described are built and the Lawrence avenue conduit is built within a few hundred feet of Clark street. The remaining portion of it is not built.

That is to collect the sewage from all the sewers that enter into the lake on the north shore within the city limits, and conduct it through the north branch of the Chicago river by way of

Lawrence avenue—the sewage from the north end of Lincoln Park upward to the Lawrence avenue conduit and another one from the north line of the city to the Lawrence avenue
535 conduit. These sewers don't go clear through the north branch of the Chicago river, except the Lawrence avenue conduit. That sewage is to be pumped in the Chicago river. The Lawrence avenue conduit is built below the lake level.

The 39th street conduit is laid out in the same way. There is an intercepting sewer starting on the south at 73d street running north on Stony Island avenue and along the lake shore to 39th street and another one from 35th street south to 39th street. These two sewers will collect all the sewage now flowing into the lake on the south shore of the city, and deliver the sewage at 39th street. This system has been built from 39th street south to 60th street and is in process of construction. The conduit on 39th street is finished with the exception of cleaning up, and the water from the lake and the sewage from that district is to be put through the 39th street conduit with pumps. The 39th street sewer is all below the level of the lake and pumps located at the lake have been provided for lifting the sewage into the south fork of the river. The population that would contribute to the intercepting sewer on the north that is connected with the Lawrence avenue conduit would amount to 28,878 by the school census. There is no intercepting sewer connected with the Fullerton avenue conduit. From the school census the population of the area that is connected with the 39th street conduit is 178,182. By the Federal census would make 16 per cent reduction, or about 150,000.

In January, 1900, and at the present time, all the sewage from the district covered by this 39th street intercepting sewer system, ran into the lake.

537 If all the intercepting sewers now in process of completion, were finished, there would be none of the population of Chicago that would have the outflow of their sewage into Lake Michigan direct from the outlet of Chicago. Some of Chi-

cago goes into the Calumet, and goes indirectly into the lake, but nothing direct into the lake.

CROSS-EXAMINATION, By Attorney General Hamlin:

The Illinois and Michigan canal was constructed some time in the forties.

These pump works were established about 1879 or 1880. They have been in operation ever since at intervals most of the time. There have been intervals when they did not operate. They were in operation pretty much all the time from the time they commenced operation up to the time the drainage canal was put in operation. They were not shut down much.
538 After being put in operation they were under control of the city of Chicago. The Illinois and Michigan canal connects with the river that way.

From 1879 to January, 1900, the north branch of the Chicago river carried sewage, to the confluence with the main river, and with the south branch. That went sometimes to one place, sometimes another, sometimes in the lake and sometimes down the south branch. When the pumps were in operation it went the same, depending on the quantity of flood water reaching the river. The south fork of the south branch reached the stock yards district. The stock yards from 1879 to 1900 were about the same size, perhaps increasing some in the actual number of animals killed there.

The per centage of sewage discharged into the canal by the pumps was variable. In dry time when there was very little or no flood water reaching the Chicago river or its branches, and the pumps in operation to their capacity, which was then not far from 45,000 cubic feet a minute, there would be none of the sewage that went into the river reached the lake, only such sewers as had their direct outlet into the lake. It would ultimately go into the canal through the pumping works.

That condition existed about twenty years. The fall from Robey street to Lockport in the drainage canal—or as far
540 as Willow Springs, was at the rate of one in forty thousand, and from Willow Springs to the controlling works,

one in twenty thousand. The fall in feet from Robey street to the controlling works, I put it, I think at 5.55, that is the bottom of the canal.

The sewers that are to finally connect at Lawrence avenue and the other points I have mentioned are partly constructed but they are not in operation and the sewage that they will carry is now going directly into the lake. I think in 1900, February and March, they had the contracts let for the construction of these sewers. Based on the Federal census the population that drains in the lake would be not far from 150,000.

RE-DIRECT-EXAMINATION, By Attorney General Crow:

The controlling works consist of seven sluice gates that
541 move in slides and are operated by certain mechanical
appliance. Each of those gates has an opening of thirty feet, clear opening. These gates were not all in use; they have not needed them; but they are there as a reserve when the flow becomes so great that they may need them. Then the early appliances relied upon for the main control now, is what is known as the Bear Trap dam, which is 160 feet long in its horizontal
section and it has an oscillation vertically of seventeen
542 feet. The dam is made out of steel—a steel caisson, and
the upper edge of it that points up-stream can be lowered or raised by the water. By letting the water in underneath the dam, it will be raised. By letting that water out into the tail race it will be lowered so that that dam can be oscillated just by operating valves, over a range of seevnteen feet.

I mean that if you put the dam down to the lowest point, it will be seventeen feet below what it would be if it was at its highest. It might not lower the water materially in front of it, it would be just pouring out as a mass over that dam, you know, a good many feet deep.

The town of Lockport is located off to the southeast of these works. The Illinois and Michigan canal lies partially between the drainage canal and the town. At this point the drainage canal is off from the Illinois and Michigan canal a considerable distance. To go to the town you would have to cross the Illinois and Michigan canal.

543 These controlling works at the Bear Trap dam were constructed for the purpose of controlling the amount of water that passed out of the canal into the Des Plaines river, and the volume of water that can be discharged through these sluice gates will more than equal the amount of water taken in at the intake of the river at Chicago.

The necessity for these controlling works arises from the fact that sometimes they would want to shut it off entirely, possibly, and sometimse when you must limit the flow through the river, and as a matter of fact that is what they have been compelled to do all the time by the United States government. They have had to cut down the flow through the Chicago river in accordance with the standard set by the Secretary of War, and it is only by means of this controlling works, that they could do that. Without these controlling works it would simply run wild. That is it would simply flow all that the hydraulic conditions would allow until it would flow all the water that could go through the river and canal under the conditions of cross section and head and fall, and all of that. In other words it would do like a river itself; it would take its uniform flow and you would have no control over it. This was a measure of precaution for the purpose of controlling the outflow of water at all seasons.

544 DR. WALTER C. G. KIRCHNER, called on behalf of complainant, examined in chief by Attorney General Crow, testified as follows:

Am a physician and have been for two years. Am senior physician at the City Hospital. 28 years old. Assisted Dr. Amand Ravold in investigating Chicago river, Des Plaines river, the Drainage canal itself; the Illinois and Michigan canal; Illinois river, Missouri river and Mississippi river. Worked and assisted mainly in quantitative analyses of the water.

545 Began working with Dr. Amand Ravold about August 10, 1899. (This witness states the manner of taking samples of water, plating, etc.

555 EDWARD JAMES RAVOLD, called on behalf of complainant, examined in chief by Attorney General Crow and testified as follows:

Am brother of Dr. Ravold. (This witness testifies as to taking samples of water, the method, etc.)

568 DR. WALTER C. G. KIRCHNER, recalled, on further direct examination by Attorney General Crowe, testified as follows:

570 (This witness identifies the detail made of the bacteriological examination at various points, testified to by Dr. Ravold, and states them to be in accordance with the original figures made by him at the time of the examination.

582 (States method of taking samples and of conveying to laboratories.)

588 DR. AMAND NICHOLAS RAVOLD, resumed the stand for further direct examination by Attorney General Crow and testified as follows:

I heard and saw the comparisons made from the data Dr. Kirchener had and those you presented to him, and will say they are the same details for the corresponding period that I have heretofore read into the record in this case.

589 JAMES J. MOORE, on behalf of complainant; examined by Mr. Jeffries:

Worked under Dr. Teichman and Dr. Ravold, for the Health Department of St. Louis, in collecting samples of water. Describes method pursued.

593 FRANK J. BROW.., in behalf of complainant, examined by Mr. Jeffries:

Resides in St. Louis. Collected samples of water for Dr. Teichmann. Describes method pursued.

598 EUGENE BRUNK, in behalf of complainant; examined by Mr. Jeffries:

Live in St. Louis. Gathered samples for the Health Department under direction of Dr. Teichmann. States method pursued.

605 JAMES GOLDEN, in behalf of complainant; examination by Mr. Jeffries:

Live in St. Louis. Am inspector in Sanitary Division of Health Department. Between months of May and July, 1900; worked under Dr. Teichmann, getting samples of water. States method pursued.

610 BENJAMIN FRANKLIN HART, in behalf of complainant; examined by Mr. Jeffries:

611 Live in St. Louis. Am water inspector for Water Department of St. Louis. From April to August, 1900, took samples of water for Dr. Teichmann. States method pursued.

616 C. V. MERSEREAU, in behalf of complainant; examination by Mr. Jeffries:

Live in St. Louis. Am civil engineer. Am assistant engineer in the Water Department of St. Louis.

617 From Jan. 22, 1900, to May of that year, I was working with men who were taking samples of water for the city chemist. States instructions given to the various collectors.

621 Explains method, apparatus, etc.

628 HENRY R. TAYLOR, in behalf of complainant; examination by Mr. Jeffries:

Live in St. Louis. Was janitor of the office of city chemist of St. Louis. (Explains method of preparing and sterilizing bottles used to collect samples of water.) I prepared all the bottles and shipped them.

633 FRANK J. BROWN, recalled in behalf of complainant; examined by Mr. Jeffries:

Identifies tags used on bottles shipped to city chemist's office from various points where the water was collected.

635 JACOB APEL, in behalf of complainant; examined by Mr. Jeffries:

Was collector of samples of water. Describes method pursued and places where water was taken.

DR. WILLIAM C. TEICHMANN, called on behalf of complainant, upon examination by Attorney General Crow, testified as follows:

640 My name is William C. Teichmann, and am forty-three years old. I reside at 3624 Shaw avenue, St. Louis. I am city chemist and have been since April, 1893.

641 I had charge of the chemical investigation of the waters of the Mississippi and the Missouri rivers and the Chicago Drainage canal and the Illinois and Des Plaines rivers which was begun along in 1899 and continued through 1899, 1900, 1901 and 1902.

The first period of investigation began on August 23, 1899, and continued until January 22, 1900.

642 I was ordered by the health commissioner of St. Louis, who is the superior official of my department, to take these samples.

Total number of samples collected during the first period was 142.

The points were as follows:

Mississippi river, Chain of Rocks, near Intake tower, 26 samples.

Mississippi river, Chain of Rocks, Missouri shore, 3 samples.

Mississippi river, Chain of Rocks, Illinois shore, 3 samples.

St. Louis water works, the uptake, 28 samples.

643 Mississippi river, Madison Landing, between Chain of Rocks and the mouth of the Missouri river, near the Missouri shore, 3 samples.

Mississippi river, Madison Landing, between Chain of Rocks and the mouth of the Missouri river, near the Illinois shore, 7 samples.

Mouth of Missouri river, 10 samples.

Mississippi river points, between Alton and the mouth of the Missouri river, 13 samples.

Mississippi river, near Clifton Terrace, between Alton and Portage, 6 samples.

Mississippi river at Elsah, near Piasa Bluffs, between Portage and Grafton, 5 samples.

Illinois river at points located, one, two, three and five miles above Grafton, 19 samples.

Mississippi river at points 1, 2, 3 and 5 miles above the mouth of the Illinois river, 19 samples, total 142 samples.

644 These samples were taken to the city chemist's office, St. Louis, and they were there analyzed by myself and my assistant, Mr. Thomas A. Buckland. From Aug. 23, 1899, for two months these samples were taken in demijohns, by holding in the hand under water.

Exhibit 16 is the character of bottle that was used in collecting the samples after two months.

647 Originally educated at Washington University, academic department. My education is chemical. I left the academic department of the Washington University and entered in the fall of 1875 the Polytechnic College of Brunswich, Germany. I studied chemistry at that college from 1875 to 1879. In the fall of 1879 I proceeded to Berlin and entered the University of Berlin, Germany. I studied there chemistry and a number of other corresponding branches, like history and literature, for general educational purposes from 1879 to 1881. In Berlin I studied principally under Prof. Ferdinand Tiemann, who is considered one of the leading authorities on water analysis, and the author of a well known standard work on water analysis. In 1881, in the summer, I left the University of Berlin and studied a half year's course in the University at Leipsic—I studied history. I then proceeded to the University of Munich in Germany and studied history from 1882 to 1885, and I graduated as a doctor of philosophy in chemistry and history in the year 1885, from the University of Munich, Germany

648 Under Prof. Tiemann, at the University of Berlin, I made a specialty of the study of the analysis of water. In 1885 I returned to this country and was principally occupied in literary pursuits until 1890. I then became private assistant to Prof. Charles O. Curtman, professor of chemistry in the Missouri Medical College at St. Louis. In 1891 I became assistant instructor of chemistry, as assistant to Prof. Curtman, in Missouri Medical College, which position I retained until 1895. In that position I assisted in quite a number of analyses of water. In 1893 was appointed city chemist of St. Louis, and have occupied that office since that time. Among the duties of the office, which are manifold, there is first of all, analytical work for the Health Department, which includes constant analysis of samples of well water and of cistern water. Some branches of it is continuous work.

644 Since this examination began, I have analyzed the water from the Chain of Rocks, not only for this litigation, but also for the water department, in order to give them a correct daily record of the water supplied to the city.

Prior to August, 1899, the analyses were made of a sporadic character. That is, they were not regular in intervals—it was only at times when the board of health just wanted to know how the city water supply was. I took samples then from the tapl and on one occasion, in 1893, in October, I took a number of samples from the mouth of the Illinois, and from various poins, about twenty-two samples, from various points

650 between the mouth of the Illinois and the Chain of Rocks, but that was only one collection made, and I consider that analytical survey of a sporadic character, and I don't consider myself justified in drawing definite conclusions of the character of the water at that time from this sporadic series of collections.

The next period begins January 23d, and ends for the largest part of the collection of the samples on October 11th, 1900. During that period 3,492 samples were collected.

Witness then states points at which samples were collected. Entire number of samples analyzed from Aug. 23, 1899, until Jan. 1, 1900, amounted to 4,000.

657 During the time above indicated, the samples were taken daily. From Oct. 12, this daily collection of samples outside of St. Louis ceased and we only collected weekly or semi-weekly after that period until November 30, 1900.

658 These bottles were tagged and the tags are here; there are about 8,400 of them.

659 The books containing the official register of the city chemist's office, of all samples of water beginning with
660 sample 148, until the present date, are stipulated to be in evidence but not to be printed. The record corresponds with the memorandum on the tags, and the register also states in every case that duplicate chemical sample was turned over to Prof. Keiser, and that the bacteriological sample collected at the same time by that collector had been turned over to the Bacteriologist.

There are five periods of investigation altogether.
661 This is the third investigation. The date particularly as far as the collection of samples at the Chain of Rocks is concerned, was from October 12, 1900, to September 30, 1901. During this period of collection analysis of samples was confined to such as were taken from the Mississippi river at the Chain of Rocks, daily, from the following points:

Illinois shore.

Missouri shore.

Intake tower.

Near Intake tower; one opposite Intake tower, from Illinois shore, and one from Missouri shore, Intake tower.

Also a sample was taken from the outlet chamber of the St. Louis water works, every day.

662 And from the top of the city chemist's office.

These samples were taken daily from Oct. 12, 1900, to September 30, 1901.

664 The next period was from Oct. 1, 1901, to Nov. 30, 1901. This was the most extensive period, or the period of the

most extensive investigation connected with this litigation. It was principally a daily collection of samples with the exception that at some points, cross-sections were taken and
665 for special scientific reasons connected with the investigation, samples at random had to be taken, but not consecutively every day, from day to day, but there was from a large number of points during this two months, daily samples collected.

665 The samples were taken from various points beginning with Bridgeport down to the intake. (See 1063-4-5.)

Tri-weekly samples were collected from Lake Michigan during this period.

666 Semi-weekly samples were taken from the south branch of the Chicago river at a point near the Chicago & Alton bridge; also at Wesley, Illinois, left, right and center section of the Illinois river. Wesley is three miles south of Peoria.

Four samples during this period at Omaha, above and below the city of Omaha.

Four samples from above and below the following cities, on the Missouri river:

Kansas City, Jefferson City, Herman, St. Charles.

Two samples were also collected from the following points:

Missouri river at St. Joseph, Mo.; Kaw river near Argentine, Kan.; from the Missouri at Wathena, Kan.

During this period occasional cross-sections of samples were taken at various points enumerated on page 666.

668 Next period extended properly from December 1, 1901, to July 1, 1902, and represents a daily collection of samples from the Mississippi river at the Intake tower and from the Missouri and Illinois shores; and also from the outlet chamber of the St. Louis waterworks and from the tap in the city chemist's office.

CROSS EXAMINATION

By Judge Springer.

671 The samples at Chain of Rocks, Missouri shore, were taken—supposed to be anywhere from 25, 50 or 75 yards. It is impossible to designate a particular point there on account of the current, but the general instruction was that the collector was to get a sample from the Missouri river current, which is generally supposed to hug the Missouri shore very closely, to get a sample of that current.

Q. Now what were your instructions with regard to the point on the opposite shore or the Illinois shore?

A. Exactly the same, only applied to the general supposition of a certain current hugging the Illinois shore there.

Q. How far was that point from the land, from the shore of the Illinois side?

A. Well, now, that varies very much according to the point taken at the shore, and it has to be left to the judgment of the collector largely.

672 My instructions in regard to that particular point was that they were to get water that was close to the Illinois shore, a certain current there with which the collector would very soon become familiar after entering upon his duties.

Q. Was there any distinction at that point between water which it was supposed by you or your collectors to come from the Mississippi river proper, or from the Illinois river in part—in other words, had the Illinois and Mississippi waters commingled at that point so that they could not be designated or separated from each other by the eye?

A. Well, we could only determine by the chemical analysis, that is, the results of the chemical analysis would demonstrate that.

675 CHARLES F. WERNER, called on behalf of plaintiff, examined by Attorney General Crow.

Collected water samples and testifies as to method pursued, etc.

684 DR. W. C. G. KIRCHENER, recalled. Upon examina-

tion by Attorney General Crow testified as to receiving samples at laboratory, etc.

686 **LOUIS SAUER**, examined by Mr. Jeffries. Collected samples of water. States method, etc.

689 **DR. W. C. G. KIRCHENER**, recalled, identifies tags on bottles.

691 **ALBERT WINSCHELL**, examined by Mr. Jeffries. Is a barber, collected samples of water. States places at which samples were collected, method of packing, etc.

697 **FRED DIESELHORST**, examined by Mr. Jeffries. Was collector of water samples. States how samples were collected, etc.

701 **THOMAS A. BUCKLAND**, examined by Mr. Jeffries. Am assistant city chemist. Identifies tags used on water samples. States the condition of the bottles when they came in; assisted in making examination of water under Dr. Teichmann.

706 **EDWIN A. SLUDER**, examined by Mr. Jeffries Collected water samples at various places and states method used and places where samples were taken.

718 Stipulation and order of court of March 3, 1903, in regard to taking of testimony.

719 **THEODORE G. RUFF**, examined by Mr. Woerner. Collected samples of water. States method.

722 **ED. BOCHERT**, examined by Mr. Jeffries. Drove the wagon that conveyed samples from Chain of Rocks to city hall, etc.

726 **ANTON KREH**, examined by Mr. Jeffries. Collected samples of water. States places at which collections were made and method.

732 **FRED B. WENZEL**, examined by Mr. Jeffries. Collected water samples. States places at which collections were made and method pursued.

736 **WILLIAM TOOHEY**, examined by Mr. Jeffries. Collected samples of water. States places at which collections were made and method pursued.

DR. AMAND NICHOLAS RAVOLD, recalled and examined by Attorney General Crow:

740 I am acquainted with L. H. Taylor's report to the city board of health of Plymouth, Pa. I never was in Plymouth. Following as to information received from report, objected to by Attorney General Hamlin. It seems from the report the typhoid fever epidemic of 1885 in that town, was caused by a person being sick with typhoid fever in January and his dejecture, urine and feces were thrown out upon the side of the mountain, with the water reservoirs down below. Here in the ice and sun of this cold region, it remained frozen until early in March when it thawed and this water containing the feces ran down, into the reservoir, and when the superintendent of the reservoir found the lower reservoir low enough to permit him to pump, or rather to turn this water into the water supply of the town, then the pumping was stopped from the Susquehanna river and this water supplied, and within an incubation period of from two to three weeks, April 9th the first case of typhoid fever appearing, this epidemic occurred.

741 Water amounting to 5,000,000 gollans in reservoir was infected by the discharges of one person.

Have been to Hamburg, Germany. They have a water filter there for their city water supply. The water is pumped from the river Elbe, the Norder Elbe. First it is carried into

742 two very large sedimentation tanks. Here the water is allowed to settle from 24 to 36 hours and it is then carried across to a series of sand filters. They have forty to fifty inches of filtering surface. The water is admitted slowly from below until the sand in this whole mass of rock, etc., is saturated with water. The water is allowed to cover the surface of it. Then the filtered water is allowed to run in so as not to disturb the filter bed too much and anywhere from 30 to 50 inches of water are allowed to stand on top of the sand. The water that first passes through the filter is bacteriologically practically the same as that which runs into it—contains the same number of bacteria.

After a time the filter begins to filter. The bacteria has this little gelatinous capsule on its cell wall which permits it to adhere to a grain of sand or to one another and in this way a glue like mass was in the sand layer of the filtering tank, or as the Germans call it, a Smutzdecke is formed. This bacterial layer now catches all bacteria and solid particles that are in
743 the water as it passes through the filter and holds them tenaciously.

The water passes from these reservoirs into what is called a clear well at Hamburg. The clear well is covered. Every few hours a sample of this water is taken. This well is walled, with masonry. The water taken from this clear well, according to the German law, must not contain more than 100 bacteria per cubic centimeter. If it does the filter is not working properly and is put out of use. There are what is known as open filters, not covered as they are in Berlin. The filter basin is open. That number of bacteria is harmless.

744 I have here chart showing the course of the typhoid fever in Hamburg before and after the filtration of the municipal water supply. On the left hand side of this chart of figures ranging from 0 to 100. This represents deaths per 100,000 of population. Along the lower margin are written in figures in ink, the years from 1880 to 1898. Then I have columns here in black and the deaths per 100,000 can be read from the left hand side of the map and also from the figures written on top of the column.

From 1880 to 1893 in May, the average death rate was 39.7 per 100,000. From 1893 to 1898 the average death rate after this filtration is 9 per 100,000.

745 Said map marked Exhibit 21.

I received information through Dr. Seibert of New York, of the New York Medical Journal, that in 1901 the typhoid death rate in Hamburg was one death to 60,000 of population. So if marked on that map it would be a very small column showing the efficiency of filtration against water born diseases.

Have seen the water supply of London. They have the oldest filters in the world, started to put them in in 1829 and are much similar to the Hamburg filter. I saw those at Lambeth and Hampstead.

746 The water is pumped from the Thames. There was a great decrease in typhoid death rate in London following the introduction of the filter system.

The water supply of Vienna is taken from the Springs in the Schneeberg mountains. They come 67 miles. When I was there they were intending to put in filters of the Wormse of Plague type.

748 The death rate from typhoid in Vienna is very low. In 1890 it was 9 deaths per 100,000 population.

Have been in Berlin and investigated their water supply from a sanitary standpoint. They have a filter water supply.

749 From 1843 to 1853 the typhoid death rate was 1 to every 900 inhabitants of the town. The first filter was put in in 1856. Now 1883 to 1893, before the bacteriologists had really taken hold of this subject of filtration, before we understood it, the typhoid death rate was 1 to 900. In the meanwhile Berlin had some shallow wells in which some of the water supply of the town was taken, but from 1892 on when the new works were put in with all water filtered, we find that in 1900 it is reported there was one typhoid case to over 50,000 in-
750 inhabitants. That is a remarkable reduction.

Have investigated the water supply of Paris, France. They have some filtered water there and water brought a long distance from springs in the mountains as high as 100 miles.

They also pump directly from the Seine. In some houses you will see two faucets. One faucet has a sign on it, "This is dangerous. Do not drink it." The other is the good water that has been filtered or that has been brought in from the mountains.

They have sand filters pretty much the same as the Hamburg and Vienna and Berlin filters.

751 I am familiar with the report of the man who made the investigations, Dr. Thorne, of the epidemic of Catterham

and Red Hill, England, in 1879. The water supply of Catterham and Red Hill was supplied by a water company which pumped their water from deep wells. Two of the wells were somewhat near together and it was decided to connect them with a tunnel or an adit, and they were working on a small tunnel for the purpose of connecting these two wells together.

One of the workmen worked from January 5th to 20th. He had diarrhoea all this time and on the 20th was so sick that he was taken to his bed and remained there. While he was at work his discharges were carried up in a bucket that carried up rock, and discharged on the surface of the soil. It was a liquid discharge and the leakage from these buckets affected the water supply. On January 19th the first case of typhoid occurred. All of the typhoid occurred in places where the water supply was had from this company. The inmates of the Insane asylum and the military forces stationed there, who received their water from an independent well, were not affected.

752 I am familiar with what is called the London Bond Street Pump Epidemic. The pump was sunk into the ground on Bond street and the water was taken by a number of people living in that neighborhood. It was said to be a good well and the water was sparkling and tasted very nicely. When this cholera epidemic was investigated by the authorities they found that close to it was a cess pool and also a sewer that carried the sewage from one or two houses near by it.

There was found to one side or near it, when this cistern or well was broken, a drain which was practically pervious, allowing the sewage to come through and also the cess pool which allowed the discharge to enter almost directly into this well. The case of cholera existed in the house that used this cess pool and the feces were carried directly from the cess pool into this water.

Witness reads from Hill's work on public water supplies, the deaths per 100,000 in foreign cities.

Witness then reads deaths per 100,000 in cities of the United States. The foreign cities have filtered water supply while the United States has not and the difference in deaths is in favor of the European cities.

756 ARTHUR C. LOOLEY, examined by Mr. Woerner. My business is grocery clerk. Was employed to collect samples of water for Dr. Teichmann. Explains method pursued, etc.

759 DR. AMAND NICHOLAS RAVOLD, resumed the stand for further direct examination by Attorney General Crow. This is a chart prepared by me. It reads as follows: Chart showing cases and deaths from typhoid fever in St. Louis, Missouri, when water supply was taken from the Mississippi river at Bissell's Point, from January, 1890, to September 28, 1894, to December, 1902, when the water was taken from the river at the Chain of Rocks. Below that is written water from Bissell's Point, January, 1890, to September 28th, 1894, five years. Cases of typhoid fever 1,268. Below that is writ-
760 ten: Water from Chain of Rocks, 1895 to 1900, five years. Typhoid fever cases, 2,490; deaths from typhoid fever, 562.

Back of that is written, with an index pointing to the percentage decrease in typhoid fever death rate 125 per cent.

That is the difference between these two points. The reason for this decrease is that when the water was taken from Bissell's Point, Harlem Creek, which drained an area containing 10,000 inhabitants, discharged its contents into the intake of the St. Louis water supply.

761 Next is water at Chain of Rocks since the opening of the drainage canal, January 17, 1900, 3 years, 3,426 cases and 588 deaths.

Water at Chain of Rocks three years before opening of the drainage canal, for 1897, 1898 and 1899, 1,807 cases; 350 deaths.

Back of that is shown increase in typhoid death rate since opening of the canal, three years, 68 per cent.

From the statistics of the Board of Health of St. Louis this chart has been made to graphically illustrate these matters.

The Harlem creek epidemic occurred in 1892.

In 1890, there were 547 cases; deaths 277;

In 1891, cases 447; deaths 160;

1892, 3,624 cases; 488 deaths;

762 1893, cases 788; deaths 215;

1894, cases 816; deaths 178.

During 1893 and 1894 the Harlem creek still affected the conditions somewhat because in high water the pumps were not heavy enough to take all of the water that is discharged on that watershed, so it ran over the dam.

1897, 433 cases; 125 deaths;

1898, 426 cases; 95 deaths;

1899, 948 cases; 130 deaths.

764 In 1899 we have a remarkable number of cases. In November, 488 cases reported and 31 deaths; and in December, 116 cases and 20 deaths, which makes this great increase here.

The river was so low in 1899 that it was feared that the lowest gates in the intake tower would not be low enough to admit enough water for the pumps, so a coffer dam was built about the intake and men put at work breaking a hole through this tower and they got down pretty low and stirred up the mud in the bottom of the river.

The result would be, of course, part of it, to stir up any bacteria, any typhoid or pathogenic bacteria in the water there.

I have no data to assist me in drawing a conclusion that

765 that was really the cause, although the cause for that particular flare in November has been ascribed to the work that was going on in October, in that tower.

I know that at that time there were dredges at work in the Illinois river below Kampsville.

766 In 1900 there were 1,213 cases, and 168 deaths;

1901, 1,101 cases, 198 deaths;

1902, 1,112 cases, 222 deaths.

Map offered in evidence as Exhibit No. 22.

767 Chicago has a population of 1,650,000 according to the United States census.

The proportion of population in the vicinity of Chicago, which also discharges its sewage into the drainage canal above Lockport, is roughly estimated at 350,000 people.

That makes approximately 2,000,000 people whose waste products are emptied in the drainage canal above Lockport.

768 There are about three ounces of solid excrementatious matter and 40 ounces of urine per capita per day. That is a low average. If each of those 2,000,000 people discharged three ounces a day the total results would be above 187 to 190 tons of solid matter, human offal.

769 Forty ounces a day would give 670,000 gallons of urine per 24 hours.

When I say sewage I mean the urine and feces and liquid matter flowing in a sewer.

The consumption of water by Chicago is 150 gallons per day per inhabitant, which would make the consumption reach 360,000,000 for the 2,000,000.

770 The dilution of sewage by waters flowing in drainage canal assuming that 300,000 cubic feet are discharged per minute is as one is to nine. The diluted sewage at Lockport does not approach in the slightest degree to the resemblance of a sanitary water.

767 The population of Chicago is given by the last U. S. Census as 1,650,000. Sewage from 350,000 people is also discharged in the canal above Lockport. This is outside of the Sanitary District. The waste products of these
768 2,000,000 people are emptied into the Drainage Canal above Lockport, 27 miles approximately from Chicago.

There are about 3 ounces of solid excrementatious matter and 40 ounces of urine discharged per capita per day. 2,000,000 people discharging 3 ounces per day would be about 187 to 190 tons of solid matter, and 40 ounces of urine a day would give 670,000 gallons of urine. That is per 24 hours.

769 The water consumption of Chicago is 150 gallons per

inhabitant per day, making something like 360,000,000 gallons per day for the whole population.

770 Based upon the assumption that the Drainage Canal was discharging 300,000 cubic feet of water per minute, we find the sewage of Chicago would be diluted as 1 to 9—that is one of sewage to nine of water.

It is readily seen by a perusal of the bacteriological resykts which have been submitted here, obtained from an analysis of samples collected daily at Lockport, that the diluted sewage at this point does not approach in the slightest degree to the resemblance of a sanitary water. The effect on fish of this water at the Bear Trap Dam was to kill them. In November 1900, 500 fish were observed passing over the dam in the space of ten minutes.

772 1900 census gives Peoria a population of 56,100.

Before canal was opened the minimum flow of the Illinois river at Peoria, according to Mr. Harmon's figures from his report to the Illinois State Board of Health, is 1,221 cubic feet. We figured it 1,200 cubic feet per second.

Q. Now assuming that the people in Peoria had an outfall of sewage equivalent to the same number of people in the city of Chicago, how many gallons per day per capita at Peoria would go into the water of the Illinois river?

ATTORNEY GENERAL HAMLIN—That is objected to on the ground that there is no allegation in the bill charging the discharge of sewage at Peoria, or any claim made growing out of any such discharge.

A. Assuming the same we would have 150 gallons per minute. Basing it on a flow of 1,200 cubic feet per minute and taking 56,100 people with a discharge of 150 gallons per head per day, that would give a dilution of 1 to 92 at the low river stage. That is the Peoria sewage. The distance from Peoria to Grafton is 160 miles.

773 With the 300,000 cubic feet per minute added by the

Drainage Canal, if that were added to the low river stage of the river, at Peoria, the dilution would be 1 to 413.

Q. If the Chicago canal water were free from sewage contamination and was emptying this Lake Michigan water in the pure state into the Illinois River at Peoria, at low stage of the Illinois river, would the pollution from Peoria, if the pollution in the sewage is in the proportion that you have stated heretofore, render unpotable the water of the Illinois river at its confluence with the Mississippi at Grafton, 160 miles below, from a bacteriological standpoint?

I mean fit for domestic purposes, drinking and cooking.

A. Well, it would reduce the danger to a minimum, that is just dilution alone, at Grafton.

JUDGE SPRINGER—I want to enter an objection to that question and answer from the fact that it does not illustrate any issue in this case, and from the further fact that there is a great deal more pollution from Peoria comes into the stream from Peoria, and the Illinois river.

774 One sixth of the sewage of persons in towns not sewered, rural districts, in proximity to rivers or the feeders there-

of, brooks and streams, eventually gets into the stream. I have a report of L. E. Cooley. (Said report is as follows):

	Flow per cubic feet per second	Urban population, census 1890	Rural population	Total population
Des Plaines River	13.21	20,354	45,247	75,601
Du Page River	32.77	5,344	10,890	16,234

776 Alton has a population of 15,000. It discharges its sewage into the Mississippi river. They have five main outlets, three of which empty into the Mississippi river, behind dikes, which quite effectually check that portion of the sewage from becoming mixed at once with the waters of the main channel of the river.

Hartford is on the Illinois shore, five or six miles below Alton, about one mile above the point where the Missouri river enters into the Mississippi river.

777 I have the average number of bacteria found in the waters of this river at these two points, Alton and Hartford.

MONTHLY AVERAGE RESULTS OF QUANTITATIVE ANALYSES OF MISSISSIPPI RIVER WATER ONE MILE ABOVE ALTON AND OPPOSITE HARTFORD RESPECTIVELY, TOGETHER WITH THE AVERAGE RESULTS OF THE TESTS FOR THE BACILLUS COLI COMMUNIS.

	January, 1900.	February, 1900.	March, 1900.	April, 1900.	May, 1900.	June, 1900.	July, 1900.	August, 1900.	September, 1900.	October, 1900.	October, 1901.	November, 1901.
Alton Bacteria	118,800	192,500	192,300	29,400	10,300	8,200	7,700	2,400	2,600	2,100	1,137	1,566
Percentage Bacillus Coli Communis	.14	.17	.51	.39	.54	.60	.52	.88	.90	100	100	.77
Hartford Bacteria	90,600	190,600	208,300	29,700	12,800	5,800	61,000	2,100	2,800	2,400	2,141	3,000
Percentage Bacillus Coli Communis	.17	.50	.52	.41	.86	.61	.55	.89	.93	100	86.4	.56

778 The sewage at Alton hangs behind those dikes and is only flushed out at times when the river is flooded. Assuming that the whole of the sewage of Alton becomes mixed with the Mississippi river water and is carried directly towards Hartford with a minimum flow of 25,000 cubic feet per second, in the Mississippi, it will be seen that the sewage of this city of 15,000 people is diluted in a minimum of over one to 70,000.

779 From these figures it will be concluded from the biological results, that the sewage of the city of Alton has no effect on the sanitary conditions of the Mississippi river water at Hartford.

Explains the nature of bacillus prodigiosus.

780 Never found this bacteria in the waters of Lake Michigan, Drainage Canal, Illinois river, or Mississippi river.

On August 31,1900, we prepared in a forty-gallon whiskey barrel, forty gallons of broth culture of this bacillus prodigiosus and grew it for several days in that barrel. On August 31, 1900, this broth, containing over one thousand million

781 bacteria per cubic centimeter, was emptied into the Mississippi river just below the mouth of the Illinois river.

On the way down on the boat samples were taken right straight along, of the Mississippi river water, the samples were collected hourly and studied. Sept. 3rd, four days later, this organism was found in a sample collected in the channel of the river at Alton, but at no other place.

Sept. 20 this experiment was repeated. A barrel containing 40 gallons of bacillus prodigiosus broth was emptied at the same point, and on Sept. 23 this organism was found in a sample collected near the Illinois shore at the Chain of Rocks. On Oct. 18 this bacterium was found in a sample from the laboratory tap in the old city hall, and on October 24 in a sample collected near the Illinois shore, Chain of Rocks.

782 One hundred and seven barrels of prodigiosus broth each containing 40 gallons, were prepared at the old pumping tation at the St. Louis water works, by Mr. E. J. Ravold, my rother, and shipped to Lemont, Illinois, and emptied in the hicago Drainage Canal on the evening of November 6th, 1901.

There were one thousand million bacteria per cubic centi-

783 meter of the contents of the 107 barrels.

All the laboratories were notified and samples were colected every hour of the day and night at the Controlling Vorks, Drainage Canal, and at Joliet, Peoria, Grafton, on the Illinois river, and the intake of the water works, Chain of Rocks.

784 Bacillus Prodigiosus was found in samples collected at Intake Tower, Chain of Rocks, December 4th, at 8:45 A. M. Another sample collected at 9 A. M. on Dec. 5, contained the prodigiosus. Found at Grafton, Illinois, Illinois river, December 6th, at 8 A. M. Found again at same place December 7, at midnight.

785 A series of experiments were made with the bacillus prodigiosus to ascertain its longevity in samples of water collected from Chicago river, Drainage Canal, Illinois river at Pekin, and laboratory tap, St. Louis. A summary of the results is as follows: (See record 85.)

787 With these micro-organisms side by side, comparative estimation of the longevity of the bacillus typhosus, and the bacillus prodigiosus, in separate samples of water collected at the same time and place, and kept under the same conditions as to sunlight, temperature and darkness, the bacillus prodigiosus in sunlight, in living waters, that is, non-sterilized waters, lived from two to ten days. The bacillus typhosus in sunlight, and in living waters, non-sterilized, lived from 24 hours to ten days.

In the dark, in non-sterilized, living waters, the bacillus prodigiosus lived from 31 to 53 days and bacillus typhosus from 24 hours to 21 days.

There is a resemblance between these bacterium. They are both bacilli, non-spore forming, and from the above table it is seen that the bacillus prodigiosus is an organism which closely resembles the bacillus typhosus in its power to resist unfavorable surroundings.

788 Q. Now doctor, I will ask you in your judgement, if typhoid bacillus coming from the out-falls of the Chicago sewers into the Chicago river and carried into the Canal, could come into the Intake tower of the St. Louis water works, still retaining its vitality?

A. That will depend upon the time it takes the waters to come from Chicago to St. Louis. But basing my conclusions upon the experiments that I have carried out, and showing that the Mississippi and Illinois river water comes into the intake of the St. Louis waterworks, I am inclined to believe it is highly probable that a typhoid bacillus can live and be carried by water carriage from the Chicago sewers into the Intake of the St. Louis water works, especially in high water conditions in the Illinois river.

ATTORNEY GENERAL HAMLIN—I will enter a motion to exclude that answer as not responsive to the question.

WITNESS—The rapidity of the current does not tend to destroy the typhoid bacteria.

Q. Well, does the volume of water into which a typhoid bacillus may be put affect in any manner its vitality?

A. No sir, it does not kill it.

ATTORNEY GENERAL HAMLIN—I move that that question and answer be excluded as not responsive.

791 In our laboratory experiments, we find that when we take water for instance from the Drainage Canal, that it contains on an average of three or four hundred thousand bacilli to the cubic centimeter. We sow typhoid bacilli in this water and for the first two, three or four days the water bacteria, not the typhoid bacilli, increased enormously, and used up the nutritive material in the flask for food. The results of this destructive action on the organic matter both solid and liquid in the water, results in the production of poisons. True toxin and enzymes and these products seem to act not only deleteriously upon one another but upon the pathogenic micro-organisms that the bacteria in the living waters die much quicker than they do in sterile distilled waters, or than in river waters sterilized.

Q. But in the water in the running streams of course there is no means of judging the results of that?

A. No, the conditions are these: That the toxine or products produced by water bacteria that are deleterious to the typhoid bacillus would be greatly diluted by the flowing water. Besides typhoid bacillus is a mover, and it can swim and get out of the way of anything that would be deleterious to it in a river.

792 Results of experiments as to the longevity of the typhoid bacilli. (See rec. 792.)

799 Q. Now from your knowledge as a bacteriologist and from the knowledge you have of the Chicago Drainage Canal, the DesPlaines river, the Illinois river, the Mississippi river, and the distances, and the speed of the streams, can you state whether or not when the water is running through the Chicago Canal with the sewage running into it, bacteria could come from the Drainage Canal into the Mississippi river?

800 A. Yes, sir. I think the bacteriological experiments indicate that bacteria discharged by the Drainage Canal, especially in high river stages, are carried into the Mississippi river by way of the Illinois river.

Q. Well, do you say that as a fact?

A. Yes, sir.

Q. Now from the same state of facts, above mentioned, as to the rivers and the relative geographical location of the Illinois river, the Mississippi river and the Chicago Canal, etc., do you say, or can you say whether or not the bacteria coming out of the Illinois river, being discharged into the Mississippi river may or do enter the Intake of the St. Louis water works?

A. I think they not only may, but they do, and I base this statement upon the bacteriological investigation that has been conducted by me from 1899 to the present time, from special experiments that were carried out which led me to assert that they do from the mixture of the waters that takes place at the Intake.

From my bacteriological examination the average number of bacteria found in the Intake of the St. Louis water works for the 1900 period— this is Mississippi river water—that is the samples contain on an average of 72,600 bacteria per cubic centimeter, and bacillus coli communis 62 per cent of the time. That is the average for the whole of that period beginning January 23, 1900, and extending to October.

801 Bacillus coli communis is a pathogenic bacteria. I don't know that it ever does destroy the potability of water. I cannot say that it contaminates water at all; it is an index of pollution. It is never dangerous to the human being except when injected beneath the skin, or when it gets out into the blood stream or lymphatic stream from the intestinal canal. It is one of the most active causes of appendicitis.

802 It (the bacillus coli communis) is not classed as pathogenic bacteria by water bacteriologists, but by the pathologists on account of the pathologic conditions which they produce, which I have already explained, (rec. 801) They are classed as pathologic when they get into the tissues. Pathogenic would be the better word. You can say pathologic too.

Q. Can you state from your examination bacteriologically of the waters in the Mississippi river at St. Louis water works, whether or not that water supply is pure or impure, and if it is impure whether it is a menace to the health of this city?

A. Bacteriologically it is an impure water; it is not a potable water, and it is unfit for human consumption. That is, it flows in the river.

803 Typhoid bacteria is considered one of the highly vitalized and hardy bacteria.

Witness relates the results of experiments made to determine the longevity of typhoid bacilli in various waters under various conditions. (See rec. 803.)

(These experiments tend to show that the typhoid bacteria lives a shorter period of time in ordinary water taken from a stream than in sterilized water.)

807 Drawing conclusions from the laboratory experiments we find that the bacteria (typhoid) live from four days to as high as 21 days in the laboratory flask, in living, non-

sterilized waters. Basing conclusions on them I would be inclined to believe that the bacilli would live much longer in a running stream, living water, than that period.

Q. How much longer?

A. Anywhere from fifteen to thirty days, and that would be a very small limitation.

808 Objection to question by Attorney General Hamlin.

Taking 20 days as the period of time of travel from Chicago to the tap in St. Louis, I think it highly probable from my experiments that typhoid bacilli discharged by the sewage system of Chicago, in the Drainage Canal, could live and retain its vitality the whole, enter the Intake of the St. Louis water works and be distributed to a user of the water sufficiently vitalized to cause disease in a susceptible individual.

ATTORNEY GENERAL HAMLIN—I move to exclude the answer on the ground stated in the objection to the question.

Witness explains various theories explaining the disappearance of bacteria in running water, such as aeration, dilution, sunlight, sedimentation.

813 (Explains method pursued and where typhoid cultures were gotten that were used in experiments to determine longevity of typhus bacillus in various waters.)

817 (Explains apparatus used and method employed in examinations and tests made for the bacillus in the waters of the various rivers during the various periods of examination.)

830 Cause of typhoid fever is typhus bacillus. Cannot be contracted except by taking the bacteria in the mouth or nose and down into the stomach and intestinal canal.

832 The usual method by which this disease is conveyed is infection by water polluted with the dejecta of typhoid fever patients containing the typhoid fever bacillus.

837 From February 8th until the 20th, 1900, the water on the Illinois shore (at the Chain of Rocks) was dark, black. The water on the Missouri shore was fairly clear. The sample

at the Intake showed about an equable mixture of these two waters, and this is demonstrated in the bacteriological examination.

Q. What relation did those dates have to the epidemic of typhoid that ensued in the spring of 1900, that you have heretofore testified about?

A. Within an incubation period the typhoid death rate ran up rapidly in this town in March. Samples were collected in February, and in March 117 cases and sixteen deaths by typhoid occurred in St. Louis, a phenomena that never had occurred previously, and I believe has not since. No such a flare of typhoid in March has ever been recorded in the history of St. Louis, as followed this mixture of this dirty water at the Intake.

I do not consider this water potable and safe for drinking purposes that comes from the Intake tower of the St. Louis water works now, without filtration or without boiling.

837 CROSS EXAMINATION

By Judge Springer.

838 While the river was high the samples from the Illinois river previous to that date, the 10th, were fairly clear, running back a definite time, but this remarkable difference in the water followed a thaw in the Illinois valley and a precipitation of a good deal of water—this whole sweeping out of the Illinois river, came. The Mississippi still remained covered with ice and the Missouri river was covered with ice, this thaw not having reached round to the entire region, and until this thaw did reach the Mississippi river above, towards St. Paul, and finally sweep down onto the Missouri and the waters of all these rivers raised then this difference could be noticed. So at a particular time the Illinois river was high this flood

839 volume was very great and the Missouri and Mississippi rivers were low and the difference in the aspects of the water were recorded.

The first marked condition of discoloration which appeared at Grafton and on the Illinois shore I think was about the 10th of February, 1900. There was a high stage of water then in the Illinois river. It was a thaw, you see, that was in February. January and February are winter months.

Our work upon the rivers indicated, and we are pretty confident about that, that the first discharge of the Chicago river through the Drainage Canal, at the opening of which occurred on the 16th or 17th of January, reached here by the 29th or 30th of January, and passed, at which time fortunately the Missouri river was very high.

I reached a conclusion as to the cause of this discoloration or polluted condition at Grafton and on the Illinois shore. It was this: This mass of filth that was in the Chicago river
and in the Drainage Canal while it was retained there,
840 after the waters of the Drainage Caanal were allowed to
stand, or the waters of the Chicago river were allowed to stand in the Drainage Canal for a time without being discharged. The opening of the canal discharged the water over the dam and came rushing down the Illinois valley and traces of it could be seen with the unaided eye for a great distance as the water traveled along. The greater part of the sediment was carried down by a sedimentation, making a black, nasty mud in the stream. It was winter and the anaerobic bacteria were not at work. Consequently they had not destroyed the organic sediment. And then I also ascribed it partially to
taking mud that was in behind the dams along the Illinois
840 river and also the muck and slime and sludge that was
put into the river by the opening of the Chicago river.

CROSS EXAMINATION.

By Attorney General Hamlin.

847 Would you, as a bacteriologist, be willing to give an opinion as to the condition of the waters in the Illinois river above Grafton in 1899, for that year?

A. For these particular samples at these particular times?

Q. No, for the year 1899.

A. Knowing the stages of the river, I could.

Q. Your opinion is simply for the dates that you took the samples?

A. Just upon the date that I took the samples?

Q. Yes, for no other time?

A. I couldn't give an opinion upon that of which I have not.

Q. From the samples that you took in the Illinois river in 1899, are you prepared to state what was the condition of these waters during that year, or any considerable portion of the year?

A. On none other than the time I took the samples.

Q. Would you, as a bacteriologist, state in your judgement as such, that that would be a fair test of the conditions of the water in the Illinois river above Grafton for the year 1899?

A. I would not.

Q. Do you know how much sewage was carried into the Illinois river from Chicago in the year 1899?

A. I do not.

Q. Do you know whether or not there was practically the same kind of sewage carried into the waters of the Illinois river from Chicago in 1899 as there is now?

A. I do not. I have no information on that subject.

848 The primary cause for the disappearance or elimination of the bacteria known as typhoid bacillus, is due to dilution and sedimentation. The other causes that have been assigned by various observers of water as the cause for the disappearance of bacteria are aeration and agitation, sunlight, oxidation and exhaustion of food supply and planckton.

Q. Do you recognize these causes also, the same as other bacteriologists?

A. I recognize planckton as probably having nothing to do with it. I have no personal experience with it; hence can not make any definite statements. Turbidity of the water has something to with the disappearance of bacteria by sunlight.

851 The effect of the sunlight as an element of the disappearance of the typhoid bacillus would be less on the Missouri river than it would be on the Mississippi or Illinois river, on account of its turbidity.

Our experiments show that the typhus bacullus has a little longer period of life in highly turbid waters than in very clear waters the difference being a few days, five or six I believe.

853 Before the Canal gets to Joliet it widens out into a lake. The water spreads out there for quite a distance, I suppose 300 yards. Part of it is run through turbines, for power and the other part runs over a little dam. There must be a dam there because there is a water fall. There is some sedimentation in that lake or basin. There must be.

855 Assuming that there was a lake at LaSalle as large or larger than the one at Joliet, and that the water moves slowly the current at this point, and through this lake or basin, I would say that there would be a sedimentation. We took samples of water at La Salle in 1901, in October and November. I know that the water spreads out in quite a little lake above Peoria. I understand there is a dam at Henry, Illinois.

856 Assuming that there is a pond or lake at Henry, there would be more sedimentation there.

In any stream of water where there are places that we speak of (lakes or basins) there will be sedimentation. At Peoria there is another lake—the water spreads out over quite an area there. The sewage of Peoria is discharged below this lake. In 1901 when I saw this lake at Peoria the current was slow, very slow. There would be considerable sedimentation there. There are three dams across the river now below Peoria. The first is Copperas Creek Dam. I have been up and down it a number of times in a launch, the Copperas Creek Dam, the dam backs the water or the water is backed up a great many miles and it makes quite a stream, navigable for large boats. In the low water season of 1901 I was in it. We had a launch drawing three and one half feet of water and occasionally it would hit the bottom and the water was running slowly at that time, and the current in the river was slow. The water was running over the dam in a good volume.

857 There would be considerable sedimentation there. The next dam is at LaGrange, below Beardstown. The water backs behind this dam for quite a number of miles back. The river at the stage I saw it several times was anywhere from 500 yards to a mile wide and the water was deep enough to have the boats run smoothly along up to Beardstown where the water was shallow. There would be considerable sedimentation there. The next dam is at Campsville. Here the water is again dammed and backs up, the current is retarded and a great deal of sedimentation will go on here in this flowing water.

858 As to dilution, calculating upon a 300,000 cubic foot flow a minute and taking all of the sewage of the two million people that discharge into it, we said there would be a dilution of one to nine, but that if four-fifths of the sewage is now discharged into the canal, as it is now claimed, the dilution would be one to eleven.

Q. Do you know as a matter of fact that a certain amount of sewage now is discharged into the canal, that was at that time discharged into the Illinois and Michigan Canal at Bridgeport?

859 A. No.

Q. Well, there is a dilution. Assuming, as I understand, that the sewage of the entire population is carried in at the rate of 1 to 9?

A. Yes.

Q. But assuming that three-fourths—of course the proportions would change correspondingly?

A. Yes, sir.

Q. And if it was only the same that had been discharged for several years, in the Illinois and Michigan Canal, why it would be whatever the proportion of its sewage discharge was to the number of cubic feet from the lake which was poured into the canal?

A. Yes, sir.

Q. There would be a greater dilution?

A. Yes, sir. There is a large volume of water dis-
860 charged into the Illinois river from its tributaries, from
861 Lockport to Grafton. Never found the typhoid bacillus
in any of the waters I examined.
862 In the epidemic of typhoid fever in 1892 in St. Louis the
source of the disease was three or four miles from the
water works. St. Louis discharges all of its sewage into the
Mississippi river, and has done so ever since the city was large
enough to have sewers. It seems to me it was 1849 that the
first sewers were built, but I am merely trusting to memory for
that. The present population is 600,000. I have been
863 told by Dr. Morgner, of St. Charles, which is located 20
miles above St. Louis, on the Missouri river, that that city
discharges its sewage into the river. I believe they had once a
typhoid epidemic there following the discharge of dejecta from
a typhoid fever patient in a hospital, which was carried into
the water supply.

865 A typhoid bacillus, if in the water of the Chicago river,
would have to travel down the Drainage Canal, pass
through all these sedimentations, lakes and ponds that have
been mentioned, be diluted with the waters from Lake Michigan and the tributaries of the Illinois and join the waters of
the Mississippi at Grafton, then join the waters of the Missouri
and pass by St. Louis.

866 Assuming that typhoid bacillus could come from Chicago, if one was found at St. Louis, I couldn't tell whether it come from the sewage of Chicago or came from some tributary of the Illinois—not even if I found it in the water. The chances are that the bacillus traveling from Chicago would lose its virulency sooner than one that had traveled only a few miles.

Q. You spoke of having examined the report made of the typhoid epidemic in Massachusetts. Where was that?

A. Well, that was a report which Dr. Sedgwick made. In that report he makes the statement that the evidence shows that there is no stream long enough to purify itself from sewage even put in at its source.

867 Q. Is it not a fact that as a result of that report, the legislature of Massachusetts passed a law providing that there should be no sewage discharged into the streams in that state less than 20 miles above the intake of water supplies?

A. I think a law of that kind did come into force, following that.

Q. Do you say as a bacteriologist that in your judgment that limitation is a reasonably safe one?

A. It is an absolutely absurd one, it is not based on bacteriological evidence at all.

868 A very small percentage of typhoid fever epidemics show the source of typhoid fever from water pollution to be exceeding fifty miles. I have one in mind. That was the dredging of the St. Clair river, and the typhoid fever epidemic following in Detroit; that has been reported by Dr. Williams. That occurred when the river was being dredged. I don't know what the distance from the original typhoid case was to the waterworks at Detroit, but I think it is more than 50 miles.

869 I have Mr. Williams' report. I understand it was something over 60 miles.

Q. Isn't that the most extreme case on record?

A. My memory serves me with no other case at the present time. I would say that 95 per cent of the reported cases of typhoid fever epidemics or a large increase of typhoid fever from water pollution, has been shown to be less than 50 miles. The sewage of Kansas City is discharged into the Missouri River after resting in so-called cess-pools for a time. I have been told that the sewage of St. Joseph, Mo., is carried into the Missouri River. The sewage of Leavenworth and the hospitals there is carried into the Missouri River.

870 There is only one safe way of purification of waters and that is by filtration.

Q. How much filtration in addition to what you have here in St. Louis, would have to be installed in your waterworks system to make it a successful system of filtration?

ATTORNEY GENERAL CROW: Objected to as irrelevant.

A. That is not known by anybody. A body of engineers and expert filter men have been at work on that problem and they have made recommendations without having carried out an adequate series of experiments on the water to ascertain the facts connected with it and nobody knows how to filter this water supply. I do not mean to say that a system of filtration could not be installed here, but it is not known how best to filter this water and what it will cost. I do not know how best to filter this water.

871 In the reservoir system we have here there is some seventy per cent of the bacteria removed from the water, to the consumer; at a definite period of 1901, we found as high, I believe as 90 to 95 per cent to the consumer, of bacteria removed.

872 I have seen the sewage discharging from Quincy, Keokuk, Rock Island, Burlington and Davenport, into the Mississippi River. I think all of them do. St. Paul and Minneapolis also discharge their sewage into the Mississippi River. I know that there are several rivers discharging in the Mississippi. Of the towns that discharge their sewage in the Missouri River, I know of Kansas City. I don't know of St. Joe by personal knowledge, but I know they discharge their sewage into the Missouri and I know Kansas City, Leavenworth, St. Charles, and Jefferson City do.

873 It is a fact that the Mississippi, Missouri and Illinois rivers are used by the inhabitants of the various towns along those respective rivers, for the purpose of depositing their sewage in each of the rivers.

St. Louis discharges its sewage into the same common drainage that the inhabitants of the other rivers do. The first sewer was constructed in 1849.

874 Population of St. Louis, within the corporate limits that discharges sewage in the Mississippi river is 600,000.

875 The water consumption is about 130 gallons per inhabitant, making 78,000,000 gallons every 24 hours.

Basing St. Charles' population at 10,000, water consumption at 100 gallons per day, they would discharge 1,000,000 gallons of sewage per day from St. Charles.

Kansas City has a population of 200,000, basing a calculation of pumping 130 gallons—or make it 100 gallons per inhabitant, would make 20,000,000 gallons of sewage per day.

876 Explains cause of typhoid fever and how that disease may be communicated. One of the means of communication is milk.

877 St. Louis gets a large part of its milk supply from the rural districts of Illinois and Missouri. In my work as sanitarian I have visited the companies furnishing milk supply. In nearly all of these places they steam sterilized the cans before sending them away or they drive them into boiling hot water with streaming steam in it before sending the cans away from the city. I never visited the Union Dairy Company and do not know whether they have any system of sterilization. They handle a large quantity of milk. If the cans are not sterilized I would say that it was a gross act of negligence, owing to the fact that there is a possibility of typhoid bacillus being conveyed that way.

878 I know that there are accounts in the literature of typhoid epidemics caused by the milk supply.

I know in the books where a man washed the milk bucket with this diseased water and not entirely drained and the typhoid bacilli got into the milk.

881 Isn't it a fact that you know that the Illinois river only contributes about one-tenth of the volume of water that is contributed by the Mississippi above Grafton and the Missouri at its mouth?

A. In these low river stages this would seem to be the case because I find that just below Grafton in the Mississippi the minimum flow of 24,858 cubic feet per second was noted on January 11th of this same year. So that would give the Illinois there 2,360 cubic feet per second. That would be about one tenth.

882 Witness is asked to verify tables showing per centage of death rate from typhoid, per cent of cases to population and of deaths to cases for the years 1897-8-9-1900-01-02.

883 The watershed of the Missouri river embraces 530,000 square miles.

884 The drainage area of the Illinois river is 27,914 square miles. The drainage area of Illinois as compared with the drainage area of the Mississippi and Missouri is very small.

CROSS EXAMINATION

By Mr. Drennan.

885 The principal water-born pathogenic bacteria are typhoid, cholera and dysentery and I found none of these in the Illinois river.

Q. Is'nt it recognized as a scientific proposition that these pathogenic germs do not thrive in sewage?

A. No, it is not entirely that way. It depends upon the character of the sewage. Some observations by different men show that the typhoid bacillus has lived as high as five months in sewage, while others but a few days. So you see it depends upon the character of the sewage at the particular time.

I made no investigations as to the sewage there in Chicago, and I cannot answer as to that.

886 The septic tank system is still in its experimental stage. For certain classes of sewage it does not seem to be entirely practical. It is very efficient in some localities and not at all so in some others.

CROSS EXAMINATION

By Judge Springer.

(Witness is asked about 32 pathogenic bacilli mentioned in the works of Abbott and Frankland.)

889 Of the list mentioned, I found in the waters of the Illinois river, the bacilli coli communis, proteus vulgaris, proteus mirabillis, proteus zenkari and I think we once found bacillus pyocaneus. I don't remember whether I found these in the Missiuri river water also. I found the proteus zenkari one time in the Missouri river water oposite Bellefontaine. I found none of the others except the bacillis coli communis. They produce no disease in man; they are non-pathogenic to man.

Q. Are they regarded as injurious to drinking water?

890 A. They are related somewhat to sewage producing, when associated with others. But not of themselves.

Q. Then your conclusion, as to the dangerous quality of bacteria in the Illinois river, was not based upon the poison, the actual germs that produced disease there, but other germs which were kindred, or sometimes found with them?

A. Yes, sir.

The same is true of the Missouri river about the mouth of that stream and of the Mississippi river above the mouth of the Illinois. I found substantially the same conditions existing in all these three rivers, only more of this sewage bacteria in the drainage canal and Illinois river than we found in these others. We found them a greater number of times.

Q. Is there any means now known of obtaining absolute proof of the hygenic quality of water supply?

A. Well, bacteriology will indicate the presence or absence of bacteria.

Q. Is that sufficient to determine the potability of the water supply itself?

A. Yes, it was used by the German government. All these

samples that I have taken and have examined must be
891 considered in the light of the stage of the river and rainfall at the time.

Q. In order to obtain a perfect, or approximately perfect knowledge of the bacteriological conditions of running water, would it not be necessary to take samples every day in the year and under precisely similar conditions for those days in order to make your calculations reliable?

A. Yes, sir, that is what we did.

Q. Every day in the year?

A. Every day in 1900 from January 23d to October 11th, I think. For 1901 during the months of September, October and November. They covered only one sixth of the year.
892 During that period of investigation in 1901, from September to November there was practically no rainfall in the Illinois river basin, and the same obtained on the Missouri and Mississippi river basins. It was a time of drouth when all the rivers were depending on the springs that were discharging into them, and they remained practically level, as I showed on the charts. The Chicago sewage has shown less after running a definite number of miles, there is less trace of it in the Illinois river than there is at higher periods. It showed fewer bacteria than were originally carried by the drainage canal after running to Peoria and then to Grafton than it did in the season either following a freshet or when the river was high but steady.

Q. Did the drainage from the farm region and from the pasturage of the country districts generally, if that was coming into the stream, wouldn't it be more peculiarly a condition created by the ordinary flow of water from Lake Michigan and the Chicago canal?

A. Yes, sir.

Q. So that would be a better time for determining the influence of the Chicago water on the Illinois water?

A. This particular time was an extraordinary time, the 1901 period was an extraordinary condition, there was very little water in the river other than that discharged into it by the drainage canal.

893 It is true that water in stream is, by all recognized standards of potability, at one time and another, the subject of contamination. Bacteriologically, absolutely pure water there is none except that of boiling springs. All water from whatever sources, save from hot boiling springs, contains more or less bacteria, from very few numbers up to large numbers. The presence of bacteria in water is not of itself an evidence of fecal pollution, but simply evidence of food supply for bacteria to grow upon. I have found bacteria in fresh fallen snow, in hail and in rain water.

894 There is no such thing as running water, such as is found in rivers and streams of any country, being free from bacteria.

895 It is true that the conditions bacteriologically considered, of the Illinois, the Mississippi and Missouri rivers at the places where I have taken samples of water, are very similar to the conditions found in rivers of similar size in this country and Europe. This is true of all the periods of which I have referred as the 1st, 2d and 3d period of investigations here. I would have been terribly surprised had I not found bacteria in these waters. The rivers generally in this country and in Europe are in such a condition as to render them unfit for water supply for cities without some kind of sedimentation or filtration. That applies to all the rivers to which I have referred in my examination here.

Q. As a bacteriologist, then, you would not recommend supplying cities with water taken from the running streams of this country without some system of sedimentation or filtration being adopted for the purpose of removing the bacteria?

896 It is possible from my observation of conditions, to prevent sewage from getting into running streams. They do that effectually at Berlin with their irrigation farms; in Glas-

gow, Scotland, I drank the sewage that had been chemically treated before it was discharged into the river Clyde; at Paris the same thing is done after it is treated, and there are well known methods of purifying sewage before discharging it into a stream.

There is a greater number of bacteria per cubic centimeter in river water during flood time for the reason that all surface soil contains millions of bacteria growing upon nutritive matter that there exists—vegetable matter—as a rule these bacteria are washed into the running streams by the rainfall, so the bacteria at these particular times are soil bacteria in preponderance as a rule.

897 This contamination is not sufficient to condemn all our running water for potable purposes because they are non-pathogenic germs. If there was any town in the vicinity of this city that had a typhoid fever epidemic and the flood came and washed these typhoid germs into the river, that would contaminate the stream. If this was thrown out on the soil or from privy vaults it would sweep out into the stream in the mass of volume of water that washed all that surface and be carried along the Lord knows how far.

898 If a mass of feces should be thrown out on the sides of a reservoir, that at any time would be a dangerous thing. That may occur at any time in all the rural districts contiguous to the rivers. At Plymouth to which I have testified, there was a reservoir but it is such a very minute thing where there is a vast volume of water.

It moves the bacteria farther apart, that is all, they are still alive and they are still dangerous.

As a chain is not stronger than its weakest link the water supply is not better than its weakest place. You ought to have a water supply that would be good at all seasons, at all times, and under all conditions.

Q. Can you have that if you take your water supply from the rivers without filtration?

A. There is danger from a river that may contain, or does contain the sewage of any community ,it is unsafe to drink and no matter how far above the sewage is thrown into the river it is unsafe to drink that water unless it receives some treatment for the purpose of removing bacteria. The danger would be greatly minimized if you eliminate the city sewage, but still the danger would be there.

899 The epidemic at Lausen, Switzerland, was caused by contamination which existed only a mile and a half away from the place of the epidemic. The same conditions existed at Chatterham, England, to which I referred. The contamination was direct in the water supply, in the well itself. At Plymouth, Pa., the contamination was direct into the water supply. The epidemic at Zurich, Switzerland, was caused by contamination of a lake in the immediate vicinity. At Springwater, N. Y., the cause of pollution was in the immediate vicinity. Lowell, Mass., epidemic was caused by contamination of the Merrimac river, close to the city. Same at Sault Ste. Marie. Epidemic of typhoid at Elmira, N. Y., in 1896, the contamination came from the Chemung river and there were some places above, the highest above being 50 miles and the nearest 16 miles, and Prof. Hill says it must have come from some of these localities. Epidemic in Paris, France, in 1895, occurred from pollution in the immediate vicinity of a camp of soldiers.

902 Same as to epidemics of San Francisco, Calif., Denver, Colo., and Middletown, Conn. Stanford, Conn. epidemic of 1895 was caused by the use of milk.

903 From the recorded instances, which are the most classes, if I may use that word in this connection, as to typhoid epidemics in this country and Europe, all of them were caused by conditions which existed in the immediate vicinity of the place where the epidemic occurred.

904 The epidemic at Detroit caused by dredging of the St. Clair river, 67 miles to Port Huron, the course of the epidemic, is the only authenticated case on record where the place of pollution and place of infection were as far apart as

67 miles. I know of no ascertained case where the infection was brought further than the case I have just mentioned.

908 November 6, 1901, 107 barrels of prodigiosus broth containing more than one thousand million bacteria per cubic centimeter were emptied in the Drainage canal at Lemont.

909 The record shows one side of a cube representing a cubic centimeter.

919 The first prodigiosus bacteria was found at the intake tower, Chain of Rocks, December 4, at 8:45 A. M. I found only one. That is, I found one colony, I believe. I don't think I found more than one in a cubic centimeter. I found another on December 5th.

920 The water was cold and the chances are that there was very little growth, if any, of bacterium as it floated down the river, it simply depending upon its inherited vitality to keep alive, so I will state emphatically that I think there was no growth of the bacteria at that time in the water. The individual bacterium put into the canal at Lemont undoubtedly floated all the way and lived.

921 Found it again on December 8 in the intake tower. Found it at Grafton, Illinois, in the Illinois river on December 6, at 8 A. M. Next sample was found by Collector Homer at Grafton, Illinois, Illinois river, at midnight, December 7th. That was all the times that I found it. I never found it again —I continued searching the tap water in the laboratory until March 1, 1902. I therefore found it twice at Grafton and three times at the Chain of Rocks, which would be five times out of 1,100 samples taken for the purpose. This bacterium has never been found in the waters of the United States.

934 Bacteria known as saprophites are useful in the arts. In the production of alcohol. In tobacco culture. In beer. In the production of butter and cheese.

938 All unsterilized milk as it is furnished in the milk cans in the market, would hvae more or less bacteria.

939 The typhoid fever germs, if found in milk, would be from

extraneous introduction as milk before it comes from the cow is practically sterilized.

942 It has never been proved satisfactorily that disease bearing germs increase in number in the water—in running water.

944 If you had one hundred men with typhoid fever discharging sewage into the river at the mouth of the Illinois river, at Grafton, the danger to St. Louis would be much greater than if one hundred men were discharging their typhoid fever discharges into the Illinois river at Lockport from the Drainage canal.

Q. Suppose that there should have been 20 persons who died of typhoid fever within the year 1900 or 1901 or 1902, and that there was a corresponding number of persons in the same vicinity in the village who, recovered from the disease and the dejecta of all persons, those who died and those who lived, was deposited in the Illinios river at Grafton, what would you say as to the probability of such a deposit producing typhoid fever in St. Louis?

A. There is a possibility of such bacteria being carried into the St. Louis intake and producing disease in St. Louis.

945 Q. Now, suppose that four persons were afflicted at the same time and the urine and dejecta were deposited in the Missouri river within 30 miles of this city would not that be a sufficient number to create and probably cause at least disease germs to appear in the St. Louis intake.

A. The small number that would reach the consumer would be extremely small from these four people, from the daily discharge of four people into the Mississippi river, which we saw in a low river stage discharges something like 24,000 cubic feet a second so the separation of the bacteria which would be discharged by 4 patients into that volume of water would be very wide apart and it is possible that some of them might be carried into the intake tower and through it into the distribution system of the city to susceptible individuals, but the danger would not be very great.

Q. Take the city of Alton, 25 miles from St. Louis. Take the same conditions, what would you say would be the danger to St. Louis from the near proximity of cases of that kind?

A. We saw that the dejecta of each one of the inhabitants of Alton when discharged and mixed with the waters of the Mississippi river passing that point would be one to 70,000 and that we trace very little evidence of the sewage of Alton at Hartford, seven miles below, bacteriologically, and consequently it would be again a very remote possibility of having bacteria coming from those patients into the intake.

946 If you were afflicted with a typhoid epidemic in St. Louis where as many as 200 persons were dying in a year during the recent years and you could not trace the cause to any other source than one which you have imagined might be in existence at Alton, would not that sufficiently account for any trouble?

A. No, I think not, sir. Two hundred deaths would mean three thousand cases at least of typhoid fever in the city and that is a great many sick at the same time out of a population of 675,000 to 700,000 with 90 per cent of the bacteria removed by the reservoirs to those who consumed the water. It would take a much larger infection than four people could produce even if above the intake. It is worthy of consideration and is a factor to be considered in this connection in trying to trace the source of a typhoid epidemic every fact must be brought to light.

From St. Charles to the intake is about 50 miles. If 20 people who died in St. Charles a year and a corresponding number of patients who survived discharged their dejecta both liquid and solid, in the Mississippi river, owing to the dilution there would be the remote possibility of the bacteria reaching the intake.

948 If a lively colony got into the intake you might get several millions into the waterworks from that source?

A. And 90 per cent taken out by the reservoirs before they got to the consumer, so it would leave a few to be distributed throughout the city.

949 RE-DIRECT EXAMINATION

By Attorney General Crow.

Dilution does not in any way destroy pathogenic germs.

Considering my knowledge of the water supply of St. Louis before and opening the Drainage canal I think the water supply at the intake tower of this city has been rendered less wholesome and safe for domestic and primary use than before the opening of the canal. I can prove it chemically and bacteriologically. Formerly the sewage remained in the Chicago river in a stagnant state, long enough to become purified, and to kill the pathogenic germs. Now the current there is three miles an hour and the chances of pathogenic bacteria vitalized and strong as they come from the bowels of an individual being carried down to St. Louis water supply is infinitely greater than when the pumps were at work at Bridgeport.

951 Bacillus carried a great distance would be less virulent, but would cause typhoid fever in a susceptible patient the same as those carried a short distance. The difference being that the disease produced by a sea of typhoid bacillus would be of more severe type than that produced by bacilli carried some distance.

953 Sand or any other filtration is only a relative preventative of typhoid fever. The effect is to greatly minimize the danger.

954 Basing conclusions on dredging such as that at Detroit, it would seem that typhoid bacilli will retain their vitality a great number of days in the sludge that exists in the bottom of a river or mouth of a river.

Where sewage is found in a stream it is presumed that pathogenic bacteria may be there also because sewage polluted water contains the discharges of human beings and if there by typhoid or other diseases among them like diseases will follow in those drinking the water. Aside from the repulsiveness of drinking sewage that comes from aesthetic reasons the real danger in sewage comes from the germs. The ordinary scientific tests as to whether contains sewage pollution are microscopic, chemical and bacteriological examinations. It takes the three to determine the potability of a water supply.

955 Authentically the typhoid bacilli has been found in running waters probably a hundred times in all the history of the world.

956 Q. As a bacteriologist and hygienist I will ask you if you consider it safe for the citizens of any city to sewer into running streams the waters of which are used for primary and domestic purposes by those below.

A. I think it is a dangerous thing to do to use that water. As I remember the conclusions of the English River Pollution Commission, which worked eight years, they were something like this—that the evidence is overwhelming that sewage polluted waters are dangerous to drink and that no river in England is long enough to purify itself of sewage, consequently of pathogenic bacteria even if put in at its source.

Q. Did you find in the waters of the Illinois, DesPlaines and Mississippi rivers coli communis in greater numbers in a flood stage than in ordinary seasons?

A. In flood stages the percentage was less than in low waters. The typhoid death rate in Chicago compared with other cities of a similar size in this and other countries, is very high. The population of Chicago according to the census of 1890 was 1,148,710. The deaths in Chicago, from typhoid fever for the years indicated, are as follows: 1891, 1,997; 1892, 1,489; 1893, 670; 1894, 491; 1895, 518; 1896, 751; 1897, 437; 1898, 636; 1899, 442; 1900, 337; 1902, 509; 1902, 597—first ten months of the year only given.

In 1893 the water was taken from the four mile crib. Prior to that it was taken from small cribs not very far out. There has been a steady increase in deaths since the opening of the canal.

961 RE-CROSS EXAMINATION

By Mr. Springer.

965 CHARLES LEWIS STEVENSON examined by Mr. Woerner. Am a traveling man. Collected water samples under direction of St. Louis Water Department. Describes method pursued and where samples were taken.

968 EDWARD H. KISER, direct examination by Mr. Crow. Am professor of chemistry in Washington University, St. Louis. Have been occupying that position since the fall of 1899. Came here from Bryn Mawr College, near Philadelphia, Pa., where I had been 14 years. Was professor of chemistry there. Prior to that time was instructor in chemistry in Johns Hopkins University at Baltimore for about 18 months. I was Fellow in Chemistry previous to that in Johns Hopkins University for two years. I was graduated from Swarthmore College, Pa., in 1880, taking degree of Bachelor of Science and took degree of Master of Science in 1881 from same institution. In 1884 took the degree of Doctor of Philosophy in Johns Hopkins University, and studied in Germany in the summer of 1884, at Freiburg, in Saxony, and in 1887 Gottingen University, and in 1894 at Heidelberg, in Germany. In Germany I studied chemistry.

969 I was called upon in January, 1900, by the Water Commissioner of St. Louis and the City Chemist, to make an examination of the waters of the Mississippi river at the intake tower of the St. Louis water works, of the Missouri river, and of the Mississippi river about the mouth of the Missouri, the Illinois river, the DesPlaines river and the Chicago Drainage canal.

970 (Witness states his experience in examination of various waters.)

972 (States how waters under consideration were examined and methods pursued.)

974 I made eight determinations in the analysis of water. First, of the total solid matter in the water; second, the

amount of free ammonia; third, the amount of albuminoid ammonia; fourth, the total ammonia; fifth, the oxygen consuming properties of the water; sixth, the nitrogen present as nitrates; seventh, the nitrogen present as nitrites and eighth, the chlorine. For the first five determinations we used the water in an unfiltered state. For the last three we used filtered water.

980 We began the analyses of these waters on January 24,
982 1900. I analysed these waters to determine the presence of nitrites, nitrates, albumoid ammonia, free ammonia and chlorine and the amount of oxygen consumed. The presence of nitrites and free ammonia I regard as of chief importance for the reason that the presence of measureable quantity of nitrites in drinking water is often regarded as a sure sign of contamination, and a chemist finding a measurable quantity of nitrites in water would condemn that water as unsafe for drinking purposes. And so free ammonia, likewise, is of great importance in judging of the sanitary conditions of the water for the reason that the first product produced by bacteria in decomposing sewage is free ammonia. We always find a quantity of free ammonia in sewage, so the chemist lays special stress on these two constituents, namely, nitrites and free ammonia. Free ammonia is ammonium carbonate, or ammonium chloride existing in the water, that has been formed by the action of bacteria upon nitrogenous organic matter. Free ammonia is absent from pure water.

983 The presence of these nitrites indicates there is decaying vegetable or animal matter in the water—and the same with free ammonia. That is the reason these two chemical substances are indication or warning to the chemist that the water should be looked upon with suspicion.

I have a record of the fluctuation of the nitrites in the reservoir of this city (St. Louis) from January 14, 1900 to October 11, 1900. We made daily analyses and from them made daily averages, and from the daily averages we made weekly averages. I have those weekly averages of the parts of nitrogen present in one million parts of water in the form of nitrites.

984 Table No. 1 is read, showing result of examination of reservoir at St. Louis water works from January 24, 1900 to October 11, 1900, and giving nitrites, parts per million.

986 The average amount of nitrites during the period from January 24, 1900 to January 31, which was the time prior to receiving the water fom the drainage canal, was .0044 parts per million.

Following is the average for the months indicated, at the same place: February, .0133; March, .0107; April, .0180; May, .0055; June, .0032; July, .0017; August, .0021; September, .0013; October, .0021.

The following is the maximum: February, week of 21st to 28th, .0240; March, week of 21st to 31st, .0130; April, week of 14th to 21st, .0260; May, week of 1st to 7th, .0097; June, week of 1st to 7th, .0040; July, week of 14th to 21st, .0021; August, week of 14th to 21st, .0035; September, week of 14th to 21st, .0016; October, week of 1st to 10th, .0021.

987 Plate No. 1, presented. Curve shows the changes of nitrites in the reservoir water of St. Louis from October 1st, 1901 to November 30th, 1901.

988 Chart is marked Complainant's Exhibit No. 23. This table and this chart show that early in February the quantity of nitrites in the reservoir water began to increase very materially, and the water of the reservoir was in a highly polluted condition. This pollution continued during March and during April. About the end of April and beginning of May the quantity of nitrites materially diminished; and then during the summer months it was low, and in October they began to increase again, in 1900. Then in 1901 we continued the analyses, and found that they were again higher.

989 The abnormal increase in February in nitrites in the reservoir water we attributed to the coming down in the Mississippi river of large quantities of sewage. As shown by analyses made at other points on the Mississippi, at Alton and Grafton on the Mississippi, and on the Illinois, it was shown that they came down the Illinois river. Our analyses point to

the Drainage canal as the source of them. The decline in May, June and July from the pollution or the falling off in the quantity of nitrites in the reservoir water in the spring months was coincident with the heavy rains and the high stages of the river. This caused a greater dilution of the large volumes of rain water flowing into the rivers—the quantity of nitrites was materially diminished in the early part of May and during June, and in the summer months the high stages continued.

990 Table No. 2 shows the weekly averages of the nitrites of the water at the intake tower in October and November, 1901. (See rec. 990.)

The maximum amount in October was in the week of October 28 to November 4, and the amount was .0084. The maximum amount in November was in the week November 11 to 19, and the amount of nitrites was .0143.

991 In 1901 there was an increase over what had been found in 1900.

When the amount of free ammonia in river water arises above .045 per million, the water is regarded with suspicion, and it is generally recognized that such water is polluted. That is not a hard and fast rule, however, that is applied under all circumstances. That will vary with the local history of the water and the local surroundings. For instance, a water might contain more free ammonia than that and it might be from a source that was absolutely harmless. To illustrate, the sale might be placed in such juxtaposition to a well or reservoir that it would cause a much higher per centage of free ammonia and be absolutely harmless from a sanitary standpoint.

992 I have made weekly and monthly averages of free ammonia in reservoir of St. Louis waterworks between January 24, 1900 and October 11, 1900, which is table No. 3. (See rec. 992.)

993 These weekly averages and also monthly averages show great increase in the free ammonia immediately after the last week in January, and this high ammonia continued throughout the months of February, March and April. After the 21st

of April there was an improvement in the water, which continued until the middle of June, and after June, there was a slight increase in July and August, and again in October. So that throughout the summer the water was much better than it had been in February and March.

996 Chart No. 2 offered in evidence.

This is a chart on which there is plotted a curve, showing the changes in the amount of free ammonia in the reservoir water, St. Louis, from January 24, to October 10, 1900. This table and chart shows a very great increase of free ammonia immediately after the first week in February. The quantities of free ammonia increased very considerably in the reservoir water in February, 1900. It extended into March and April and began to diminish then just as previously the nitrites were diluted by the spring rains, so we find that the ammonia was diluted and the quantity found in the reservoir water was very much less during the spring and summer months than it had been immediately after the opening of the Drainage canal. This increase was caused by pollution which we traced to Peoria and farther beyond Peoria up to Joliet and Lockport.

997 I made averages of the free ammonia found in the intake of the St. Louis waterworks during the months of October and November, 1901. (See rec. 998.)

999 For table No. 5 see rec. 999.

This table shows that there was a decided increase in February in the number of nitrates, and also in March. Then a gradual decrease in April and that decrease became more pronounced in May. There was a slight increase in June, and a decrease in August and September. In October we find the value very near the same as at the beginning. The increase began about the time when the water of the Drainage canal reached St. Louis. Then again as in other cases, when the spring floods came, there was a diminution in the quantity of nitrates found in the reservoir water.

1001 Table No. 6 is a record of the nitrates found at the intake from October 1 to November 30, 1901. Plate No. 3 contains a curve showing the changes in the amount of nitrates found in the reservoir water. There was less nitrates in 1901 that in 1900. This would indicate that the water was more impure because the organic matter had not been completely oxidized. There were more nitrites but less nitrates in the water examined in 1901 than there was in 1900.

Exhibit 25 offered in evidence.

1003 The fourth form in which nitrogen is found in water is as albuminoid ammonia. That is not found in water in its natural state free from pollution. It is the product of decomposing nitrogenous organic matter. That albuminoid ammonia would be derived from both vegetable and animal matter in water. The reservoir water of the city of St. Louis is turbid at nearly all times of the year. That means that it contains washings of the surface of the earth, vegetable matter that has been carried in by rain fall.

1004 I made an investigation of the reservoir water to determine the quantity of albuminoid ammonia contained in it from January 24, to October 11, 1900.

Table 7 shows the average results.

1005 Maximum results for same period.

1007 Table 8 shows the results of examination at same place for months of October and November, 1901.

Plate No. 4 contains a curve showing the changes in the amount of albuminoid ammonia in the reservoir water.

According to these figures the maximum pollution occurred in March and April, 1900.

1008 The minimum was about the middle of June, 1900. There was an increase after that again in July and in August, and it remained pretty high in September and in October.

Taking all of the result of the chemical analyses made by me in the period from January 24 to October 10, 1900, the conclusion is that the water became suddenly badly polluted about the first week in February, as is shown. That is shown by a very large increase in the quantities of free ammonia and nitrates in the reservoir water and this pollution continued during the months of February and March and began to diminish in April. This was coincident with the increase in the volume of the rivers. In the succeeding year the analyses show that the water was certainly in no better condition and as far as nitrites and free ammonia are concerned, the water was more polluted in 1901 than in 1900.

Complainant's Exhibit 26 offered in evidence.

1009 This water would not be classed as a safe drinking water owing to the large amount of decomposing organic matter in it. The warm weather of the summer assists in oxidization in water. All chemical changes proceed more rapidly at higher temperatures than lower temperatures and the bacterial action is greater in the warm seasons of the year.

1011 When we find free ammonia and nitrites present in considerable quantities we regard the pollution as of animal origin and caused by sewage. Albuminoid ammonia on the other hand is not in itself so characteristic of polluted waters because albuminoid ammonia may be there of vegetable origin. Nitrogenous organic matter is the starting point from which the albuminoid ammonia as ammonia is gotten out of the organic matter in water by treating it with an alkali and by potassium permanganate, and in that way we distill off ammonia from the organic matter which is not there as ammonia in the water. We decompose what organic matter is left in the water by chemical agents and measure the ammonia that distills over. For that reason albuminoid ammonia is not an index of any particular pollution in water.

1012 There is a lower form of pollution of water that contains nitrates and nitrites. The nitrites are a final product. When we find very little ammonia and no nitrites, and a good deal of nitrates, we know the water has been polluted at one time, and it has gone through the process of oxidation so the pollution has been rendered comparatively harmless. The oxidization is brought about by bacteria, we look upon it as a process of the transference of oxygen from the air to the organic matter in the water so that the complex organic substances are resolved into simple inorganic material. I look upon the original form of polluted matter in water as a complex combination of carbon, hydrogen, oxygen and nitrogen. That would represent, for instance, albuminoids, albuminous substances that are in water, compounds of that kind are in sewage, and the bacteria break up those substances and we get ammonia, a part of the nitrogen is evolved as ammonia and then afterwards the bacteria transfer the oxygen from the air to the nitrogen that is there, forming nitrites and then transforming the nitrites into nitrates, by adding still more oxygen. The analysis of the water that I made at the intake of the reservoir was for determining the presence of these four bodies, nitrites, free ammonia, albuminoid ammonia and nitrates.

1013 I also examined for the purpose of determining whether there was chlorine in the water. I have the record of chlorine at different points. I made a comparison of the water on the Missouri and Illinois shores opposite the Chain of Rocks for the purpose of determining whether the river at the intake was of homogeneous character, whether the water was of the same character on both sides of the river. I found a marked difference in the character of the water, chemically, water taken at the Missouri shore opposite the Chain of Rocks and water taken at the Illinois shore opposite the Chain of Rocks. I found that there was a difference in the nitrites.

Table No. 9 shows the parts of nitrites per million from January 24 to October 11, 1900, at the Missouri shore and at the Illinois shore opposite the intake.

For comparison of the water on Illinois and Missouri shores, see rec. 1014.

1017 Table No. 10 shows result of examination for nitrites at same places for October and November, 1901.

1018 Plate No. 6 shows a curve giving the variations in the amount of nitrites at the Illinois shore opposite the Chain of Rocks. Plate No. 5 shows the variations on the Missouri shore. These two plates were made to illustrate the examinations as disclosed in table No. 9.

Plates offered in evidence as Complainant's Exhibits 27 and 28.

1019 It will be seen that the nitrites in January are nearly twice as great on the Illinois side of the river as on the Missouri side. They begin to approach one another in February. They are about equal in March, but in April the quantity on the Illinois shore is twice that on the opposite side and this increase was maintained throughout the summer and it became six times as great in September and October, 1901. In February, 1900, there was a rise in the Illinois river coincident, I think, with the coming down of the water of the Drainage canal. From my recollection the Missouri was low and the Mississippi river was low. During the period that we made the analyses there at the eastern shore of the river, the water was from four to five times more polluted than the water on the Missouri shore as shown by these nitrites—by the quantity of nitrites.

1020 From the fact that the amount of nitrites in the reservoir was greater than that in the Missouri river on the Missouri shore and less, somewhat, than that on the Illinois shore, we naturally conclude that it was a mixture of the two waters—in fact not only the nitrites but all of our determinations showed that the water taken in at the intake is a mixture of those two waters. The chemical analyses indicate that the water on the eastern shore at the intake tower is Mississippi river water and the water on the western shore is Missouri river water.

Now on the Illinois shore in January, 1900, the average amount of nitrites was .013 and in February it went up to .0187 and it came down somewhat in March but it went up very high in April, .308 and gradually came down during the summer but throughout the entire summer it was from four to five times as great as on the Missouri shore. The average value of the nitrites was .0068 in 1900; in September, 1901, it was .0125, nearly twice as much. Comparing the analyses made at Bellefontaine with the analysis at the point opposite the intake on the Missouri shore it discloses the fact that the water running along at the point on the Missouri shore of the intake is Missouri river water.

1021 I made an analysis at Hartford. The anaylsis showed that was Mississippi river water. I have a table showing the average of free ammonia on each side of the river at the Chain of Rocks. It is table No. 11. (See rec. 1021-2.)

1024 Plate No. 7 shows a curve giving the variations in the amounts of free ammonia at the Missouri shore at the Chain of Rocks. Offered in evidence as Complainant's Exhibit 29.

1025 This plate No. 8 shows the same thing for the Illinois shore at the Chain of Rocks. Offered in evidence as Complainant's Exhibit 30.

Table No. 12 shows the average amount of free ammonia found on each side of the river opposite the intake tower of the St. Louis waterworks in October and November, 1901. (See rec. 1025.)

1026 These tables show that much larger quantities of free ammonia are found on the Illinois side of the river during the months of January, February, March and April. During the remaining months both sides are practically alike as regards this form of nitrogen.

The analyses made in 1901 shows the quantity of free ammonia was greater on the Illinois Shore than on the Missouri shore.

Table No. 13 shows the amount of nitrites found opposite the intake, first on the Missouri shore and second on the Illinois shore. (See rec. 1026.)

1030 Nitrates found at same place in October and November, 1901. Plates 9 and 10 contain curves giving changes in amount of nitrates at Missouri shore and Illinois shore, Chain of Rocks. Marked Exhibits 31 and 32 for Complainant.

1031 There were more nitrates as a rule on the Illinois shore than on the Missouri shore.

Considering all the facts heretofore set out, with reference to my chemical work, the water is most polluted from a chemical standpoint on the Illinois side.

In regard to the sanitary character of the water, the Missouri shore is the better water.

The chemical analyses showed that the water on the Illinois shore is Mississippi river water; and the water on the Missouri shore is Missouri river water.

The chemical analyses showed that the water in the reservoir was a mixture of these two waters.

1032 From a sanitary standpoint the water of the reservoir is better than the water from the Illinois shore at the intake. The water in the reservoir is worse than that of the Missouri shore.

1033 (Witness explains mathematical method of determining the proportion of each of the waters that constitute the reservoir water daily.) By applying that method I can determine the proportion of each of the waters, that constitute the reservoir water daily. They vary from day to day.

1034 As far as analyses enables me to judge there would always be Mississippi river water in the reservoir because it stands in the settling basins for several days and there is a constant mixture there of the two waters.

My analyses show that as we go up the Mississippi river we find the water is badly polluted until we get above the mouth of the Illinois. Above the mouth of the Illinois the Missisisppi is in a very much better condition.

1035 The water of the Mississippi river above the mouth of the Illinois and the water of the Missouri at Bellefontaine they are both fairly good streams from a sanitary standpoint. The nitrites in the Mississippi river above Grafton were lower than the nitrites in the Illinois river above Grafton, and also the nitrites at any subsequent place in the Mississippi river below Grafton, namely, at Alton, and at Hartford, and at the Illinois shore, Chain of Rocks. The nitrites are quite low at the Missouri shore, Chain of Rocks. In the Mississippi river the nitrites are lower above the mouth of the Illinois and are considerably higher just below the mouth of the Illinois. The nitrites are less in the upper Mississippi river than they are at the intake.

1036 Table No. 14 shows the analyses of the waters on the Illinois shore, at Alton above the sewage of the city and above Hartford above the sewage of the city, for nitrites. (See rec. 1036.)

(For October and November, 1901, same places, see rec. 1040.) These averages show that with very few exceptions the nitrites were higher at Hartford than they were at the Illinois shore, Chain of Rocks, and they were higher at Alton than they were at Hartford. The Mississippi river is more impure above Alton than it is at Hartford, below Alton.

1041 The sewage of Alton apparently has no effect upon the condition of the river at Hartford. Its dilution is so great that it produces very little effect upon the character of the river as a whole. Our analyses shows more nitrites in 1901 than in 1900.

1042 My analyses shows that the nitrites increase as we go up the Illinois river. They are higher in the Illinois river above Grafton than they are in the Mississippi river above Grafton. The Mississippi river above Grafton is in a better condition than it is at the Chain of Rocks. The chemical analyses show that the pollution of the Mississippi comes from the Illinois river.

If it were not for that pollution by the Illinois river, the water of the Mississippi river opposite the intake would be very similar in character to the water on the Missouri side of the Mississippi opposite the intake as to the free ammonias and nitrites. The waters would be almost the same and there would be a higher chlorine found on the Missouri shore than on the Illinois shore for the reason that the Missouri river always contains a larger quantity of chlorine—chlorides, than the Mississippi, but from a sanitary standpoint, the water from the Mississippi river above the mouth of the Illinois, is very similar to the water of the Missouri river, and were it not for the inflow of the waters of the Illinois river, the Mississippi on both sides of the river at the Chain of Rocks, would be of equal sanitary character. It would be a good drinking water on both sides. As it is now the Illinois comes in and carries with it the nitrogenous organic matter which we find in the river at Grafton and at Alton and at Hartford, and on the Illinois shore at the Chain of Rocks.

1043 The Missouri and Mississippi rivers run through practically the same kind and class of agricultural region and the land in the drainage area of those two rivers for the first 1,000 miles of each stream is practically used for the same purpose by a similar class of people.

Plat No. 12 is intended to show the variation in the quantity of nitrites found in the Illinois river at a point above Grafton, and also at another point above Peoria.

1044 The lower curve gives the average amount of nitrites at a point above Grafton in the Illinois river.

The upper curve gives the amount of nitrites in the Illinois iver at a point above Peoria, throughout the time of the anlyses extending from January 24 to October 11, 1900.

Offered in evidence as Complainant's Exhibit 33. I made n analysis of the waters of the Illinois river above Grafton.

Comparing the values found for nitrites and also free amnonia, the value found for these substances at Grafton with the ame values found at a point above Alton, we find higher values, niformly above Grafton, than we do at Alton, showing that as e ascend the Illinois river the impurities constantly increase.

We have tabulated the daily analyses of the waters taken at eoria. We find that at Peoria the amount of pollution was ery great and as we go up still further to Joliet and Lockport he analyses showed that the water is simply sewage, and the nalyses there for free ammonia and nitrites are such as one btains by analyzing sewage. Began analyses at Peoria and

Grafton on January 24, 1900. At first we found less nitrites at Peoria than we did at Grafton, in January.

1045 After the opening of the Drainage canal the nitrites at Peoria increased, and were greater in number than those found at Grafton.

I conclude from these analyses that before the opening of the Drainage canal there was sewage matter in the waters of the Illinois river, but there was greater oxidation in the region above Peoria and immediately below Peoria—all along the river there was greater oxidation. That was shown by diminution. That was because it moved more slowly. The rapidity of the current retards oxidation. Before the opening of the canal, the movement was slower and while the water was impure above Peoria, we found a smaller quantity of nitrites there, showing that the oxidation had proceeded further, and then after the opening of the Drainage canal the quantity of nitrites at Peoria increased enormously, and they kept on increasing throughout the time that we made these analyses, and from that I conclude that the effect of the opening of the Drainage canal was to wash these oxidized materials further down the river. The region of bacterial action, and the conversion of nitrogenous organic matter into nitrites was moved much further down the Illinois river and into the Mississippi river below the mouth of the Illinois.

1046 The analyses made in 1901 showed that the same state of affairs existed. The quantities of nitrites found above Peoria were still very considerably greater than the nitrites found in the Illinois river above Grafton.

My analyses showed that the Illinois river above Grafton was more impure in 1901 than in 1900 for the corresponding months.

1048 Comparing the amount of decomposed sewage in the Illinois river at a point above Peoria in January, 1900, with that supposed to be there in the early part of September and October, 1900, I would say it was eight of nine times as

ich in September and October as compared with January,
00. That is shown by the red curve on the chart, which con-
ntly rises throughout that period. The impurities are some-
at diminished as they come down the Illinois river. So far as
analyses go, there has been a decided increase since the
ening of the canal in the amount of impurities that come down
Illinois river. In my opinion these impurities are not suf-
iently oxidized to be converted into harmless products by the
time they reach the Mississippi and the intake tower.

49 As a chemist and from my chemical examination of these
waters, it is my judgment that this pollution and the con-
mination from the Chicago river continues down through the
ain of Rocks, a portion of it finding its way into the intake
er of the waterworks and thence into the reservoir. In my
nion and from the analyses of these waters, the water supply
St. Louis is contaminated by the Chicago Drainage canal and
sewage emptied into it by the city of Chicago. The volume
water going down the Illinois river is greater since the open-
of the canal. The effect of this in disposing of the sewage
ses it to be pushed further down the Illinois river and into
Mississippi river in greater quantities than before the open-
of the canal. It acts to prevent sedimentation.

The sedimentation would be less now than before the waters
he canal were turned into the Illinois river because there is
ore rapid current which carries the suspended matters fur-
r down in the stream and gives less opportunity for sedi-
mentation.

9 The water at the intake is a mixture of Mississippi river
and Missouri river water. My chemical analysis discloses
the Missouri river water is far superior to the Mississippi
r water opposite the intake. The Missouri river water con-
s a larger proportion of common salt than the Mississippi
r water. I think that affects the flavor of the Missouri river
er. It has been found that one of the tributaries of the Mis-
i river that runs in from Kansas flows over salt beds and
gives it a large proportion of common salt, and that water

mixing with the Missouri gives it a high proportion of
1051 salt. There was a decided increase in the impurities of the water in the reservoir after the opening of the Drainage canal. There was a coincident increase in the impurities of the water of the Mississippi at that time, as shown by all these curves, or nitrites and free ammonia that have been exhibited. In the month of May, 1900, there was a marked improvement in the reservoir water, this improvement being coexistent with an improvement in the Mississippi river water.

I attribute the great improvement of the waters of running streams in spring and summer first to the greater oxidation which takes place in warm weather; secondly, in these waters, to the much greater volume of the streams. Throughout the time of this examination analytical results show that the water on the Illinois shore at the Chain of Rocks was in an unsanitary condition. It was water that would be condemned by water specialists. The figures for nitrites and free ammonia are beyond those that are allowable in a potable water.

1052 In potable water the average or maximum amount of free ammonia allowed is .05—when it goes above that the water is to be regarded with suspicion. If the albuminoid ammonia goes above .2 parts per million, then there is so much organic matter in the water that the conditions are favorable for the growth and development of disease germs. Then, if there are measurable quantities of nitrites, if you can measure the nitrites, that is express the result in numbers, we are usually inclined to condemn such water. If we can at all measure the amonuts of nitrites we condemn the water, as good drinking water has no nitrites in it, and whenever the chlorine goes above the normal amount, that is indicative of sewage pollution.

1055 Witness gives maximum amount of nitrites in water at Joliet in March, 1900, and extending until Oct. 11, 1900.

1056 Witness states the amount of free ammonias at same place and same dates.

1057 Same date for Lockport.

Tables No. 15, 16, 17 and 18 show results above indicated.

1059 Witness states maximum amount of nitrites found at Peoria. Also free ammonia.

1060 Above are read from tables 19 and 20.

Witness gives results of examination for nitrites at Drainage canal, off Pauline street.

1062 Result for chlorines at same place and dates.

1063 Free ammonias, same place and time.

1064 From these analytical results we see that the water of the Illinois river was more highly contaminated with nitrogenous organic matter at Joliet than it was at Peoria and likewise at Lockport there was a greater contamination than at Peoria. Now our results show higher values for free ammonia nitrites at Joliet than they do at Lockport. This I account for by the fact that the samples at Joliet were taken immediately under the Illinois and Michigan canal that passes over the river at that point. The results for Joliet show, or rather the analyses show, that it is sewage. It cannot be called water. The samples we have were really to be called sewage instead of water and at Lockport while the proportions were less than at Joliet, nevertheless we must still call it a somewhat diluted sewage.

1065 Now I notice further that sevaral months after our analyses began along in the spring months, the quantities of nitrites and free ammonia diminished both at Lockport and at Joliet. This is accounted for by the outflow of the water of the Drainage canal. At Lockport the free ammonias diminish from 2.437 down to 1.411 in June. We find that they again increased and in the subsequent year, 1901, they did not diminish below 1.239, showing a partial improvement. In other words, after the opening of the Drainage canal, this concentrated sewage at Lockport and Joliet was diluted. That in portion is the result of the analyses. That before the canal was opened there was concentrated sewage there and that after the canal was opened ther was diluted sewage there and the the results obtained at Peoria and points further down the river show that this sewage from Lockport and Joliet had been washed further down the river. My analyses show that this river was contaminated before the investigation. The river was polluted with sewage long before the opening of the Drainage canal but after the opening of the canal the sewage was diluted with water and carried farther down. We found at Grafton much higher nitrates and free ammonias after the opening of the canal than before and that in my mind, is evidence of the flushing down of the sewage matter which had accumulated at Lockport and Joliet and in the upper regions of the river, by the opening of the canal.

1066 Plat No. 11 was made by me. It contains curves of the quantities of nitrites in the Mississippi river above Grafton, at the Illinois shore, Chain of Rocks, at Hartford and at Alton and also in the Illinois river above Grafton. Those are the quantities of nitrites that have been read off in the table that have been platted on this chart.

Offered in evidence as Complainant's Exhibit 34. These examinations disclosed that in the Illinois and Mississippi river the water had a decided odor of sewage as here recorded.

Witness describes the various odors of waters in the Illinois river.

1069 The water of the Illinois river above Grafton has a musty smell or a smell of sewage, and that from the Mississippi above Grafton has the odor of earth, earthy or clay like smell.

1072 The chlorines in the Illinois river above Grafton steadily increased. I have here a table giving the average values of chlorine in the Illinois river above Grafton, above Peoria and at Joliet and at Lockport. We see a steady increase of chlorine as we ascend the river to Joliet. The Lockport samples show less chlorine than at Joliet. The explanation I give for that is that the sample at Joliet was taken immediately under the canal, under the Illinois & Michigan canal and probably contained water from that canal.

The nitrites are decidedly higher at a point above Peoria than they are at Grafton. They are lower in the Drainage canal, showing there has been less oxidation, and I think they are a little lower at Lockport than they are at Joliet. That

1073 shows that there is more crude sewage in the canal than
there is at points further down. The nitrites being
formed gradually, free ammonia is first formed by the decompos-
ng sewage then the oxidation processes set in and gradually
orm nitrites, so we find more nitrites at Peoria than we do at
some of those higher points, at Joliet or Lockport. There hasn't
een oxidation sufficient to produce large quantities, but there
re larger quantities of free ammonia at the higher points than
t the lower points.

This map shows the Illinois river connecting the Drain-
ge canal with the Mississippi river at Grafton; then it shows
he Mississippi river below Grafton, at Alton and at Hartford;
t shows the flowing in of the Missouri river at Hartford; then it
races the Mississippi river down to St. Louis. The map is an en-
argement of the map of the State of Illinois, taking only the Il-
nois river and the Mississippi river and these rivers. On the
ide of this map are given the averages of the condition of the
ater, first before the opening of the canal, viz: in Jan., 1900, at
he reservoir. First the table shows the condition of the water
at the reservoir in St. Louis in black letters, the amounts
074 of free ammonia, nitrites and albuminoid in January,
1900, and then below the values obtained for the same
ubstances, in February, 1900, after the opening of the Drain-
ge canal. These are averages taken from the tables we have
resented. For instance the free ammonia before the opening
f the canal averaged 0.111; after the opening, 0.210. The
itrites averaged before the opening 0.004 and after the open-
g 0.013. Albuminoid ammonia before the opening was 0.214
nd after the opening 0.271. It shows a doubling of the free
mmonias and trebling of the nitrites and some increase in
e albuminoid ammonias in the waters of the reservoir in Feb-
ary over what there was in January. That was in the reser-
oir of the St. Louis waterworks. The same table is shown
here for the various points on these rivers.
78 The frequent or sudden changes of nitrites and free am-

monia and chlorine in streams is looked upon as indication of pollution. The sudden changing in the nature of water is always to be regarded as suspicious, because it shows that there is sewage pollution. Sewage brings about changes in the composition of waters much more readily. These fluctuations vary more in samples taken at the same point in a stream charged with sewage pollution than you find in a stream containing vegetable or organic matter. Vegetable organic matter is much more stable than animal matter; that is very much less stable and we are apt to find greater changes and sudden fluctuations in the free ammonias and in the nitrites in sewage polluted waters than water containing vegetable organic
1079 mats. The waters of the Mississippi river above Grafton
and the Missouri above the confluence of the Mississippi are much more stable than the water of the Illinois river or of the Mississippi river below the mouth of the Illinois.

Map offered as Complainant's Exhibit No. 35.

1080 CROSS EXAMINATION by Mr. Johns:

Arrived in St. Louis and took up my duties as a chemist September 20 1899.

Before I commenced these analyses I had not traveled up the Missouri river any to examine the character of the soil
1081 and the locality from which the Missouri waters came.
Nor up the Mississippi, nor up the Illinois. I have since traveled up the Mississippi with a view of examining the soil and the water and the sources of the water. Have not traveled up the Illinois, never was at Joliet or Lockport. I have no personal knowledge of the physical situation of the waters and the origin and derivation of the waters of which I have been testifying.

Q. Isn't that knowledge regarded as important in making up a judgment as to the water?

A. Only in so far as the water is of different origin from that which we have examined in this case. A spring with water or a well water it is especially necessary to know the surroundings, the country, the soil and the character of the buildings, and so on, with that kind of water but the topography of the country in general through which the Illinois river runs has been described so frequently in reports by various scientific bodies and I have read those descriptions so that I have been able to form a very clear opinion on that point. But I have no personal observation of it whatever.

1083 Describes laboratory in which analyses were made and method pursued.

1087 Unless water is liable to a chemical change if kept any length of time at a different temperature than that at which it was collected.

1088 If kept at a lower temperature than that at which collected would slowly convert nitrites into nitrates and free ammonia into nitrites, but this change would be very much less than if the water had been kept at the original temperature.

The Mississippi river water has considerable matter in suspension. That would settle if allowed to stand. It would vary according to the length of time it is allowed to stand in the reservoir. A glass tube full of water from the intake two feet high, being allowed to stand for four hours, 75 per cent of the solid matter would settle. That would be at least 50 per cent of the original weight of the water.

1090 Have never allowed the water to settle with a view of determining the weight of the matters in suspension. Then there are solids in solution.

1095 There is not a very definite standard of potable water.

1096 The standard of potability for river water is given in our text books something like this: Free ammonia not above .06 parts per million; albuminoid ammonia, if it goes above .18 that shows that the nitrogenous organic matter in that water has approached the danger limit. Nitrites, .001 or .002 parts per million condemns the water because it has gone beyond the limit—measurable quantities of nitrites condemn the water.

1097 If the chlorine runs higher than the average for that section of the country then we suspect sewage contamination. The averages are from 15 to 16 parts of chlorine in the Missouri.

Q. Now then at 23 the waters of the Mississippi become unpotable?

A. No. If it runs very much higher than that we would say it was.

Q. Say it was 50?

A. Yes, we would suspect then sewage contamination.

Q. Now, when you read the figures, I think you read that there were .1112 parts per million of chlorines in the Missouri river off the intake tower at the Chain of Rocks on the Missouri shore.

A. That must be a mistake. There is no such state as that occurring in the Missouri shore. It runs from 10 to 23 parts per million.

1101 In regard to your algebraic formula for determining the relative amounts of two sources of water in a given place at a given time. (Certain algebraic equations are presented to witness.)

Q. Well, if the fact was independent of the algebra that the Illinois river at Grafton at that time was less than one tenth of the Mississippi in volume, your mathematics are not of much account?

A. Well, it shows that as far as the nitrites are concerned, one-fifth of the nitrites were furnished by the Illinois river and four-fifths by the other.

Q. That is precisely to the point I want to bring it. Your algebraic formula does not represent the amounts of water at all?

A. They represent the amounts of water that are necessary to furnish that constituent to the Illinois.

1102 It means that that proportion of the whole, that much of the other water, is required to furnish that much nitrites.

Q. So that it is a calculation of the comparison of pollution as to a certain element and not a determination of the actual volume of water?

A. It is not an actual determination of the volume of water.

Q. What you meant to attempt to do with that and what you do as far as the mathematical formula is concerned, or algebraic formula, is to determine that if at a given point there are .0120 of free ammonia and at some other point a certain other number of parts and a certain other point a certain other number of parts, these two confluent sources furnish a certain ascertained amount of free ammonia at the given point?

A. Yes, sir. And that is theory and not actual water.

Q. Now, with the waters of the Mississippi and Illinois mixed bearing nitrites into the intake tower and therefore into the reservoir at St. Louis of four parts of nitrites for the Mississippi and one for the Illinois, and supposing at the same time that of the total water going into the intake tower the Missouri furnished three-fourths and the Illinois and Mississippi combined one-fourth, which is your algebraic equation here, that was the conclusion at which you arrived. A. Yes, sir.

CROSS EXAMINATION by Judge Springer:

1103 Q. Now, what proportion of the Illinois nitrites under those proportions got into the intake tower, what amount?

A. Well, if the Illinois furnished one part to the four parts of the Mississippi, which it never does, the Illinois always furnishes more than the Mississippi, but making this assumption one-fourth of the nitrites furnished by the Mississippi would come from the Illinois, and since one-fourth of the nitrites would come from the reservoir, come from that, one-fourth of one-fourth is one-sixteenth, therefore, one-sixteenth of the nitrites in the reservoir would come from the Illinois.

Q. Why do you say that the Illinois never does furnish one part of nitrites to three or four parts of the Mississippi?

A. My analyses show and all the analyses that I have seen of the water at the mouth of the Illinois and Mississippi, show invariably higher nitrites, especially in the winter time. The Illinois having greater nitrites than the Mississippi.

Q. Certainly, but when one-tenth of the volume comes out of the Illinois of the volume out of the Mississippi to make a total at the Chain of Rocks then the proportion of the nitrites to the whole body is much less for the Illinois than for the Mississippi?

A. Yes, the proportion that came from that, certainly.

GENERAL CROW: Let me understand. You and the witness don't understand each other. You mean the proportion of nitrites in the whole body of water, the combined waters at the intake, that is what you mean? A. Yes, sir.

1104 Result of examination of water of Missouri river at Bellefontaine, for chlorine for the year 1900.

1105 Average same months for nitrites.
Average same months for nitrates.
Average same months for free ammonia.

1106 Average same months for albuminoid ammonia.
Above are monthly averages.

1107 The total solids run very high. The Missouri often is very muddy and taking it unfiltered and simply shaking it up we got an enormous weight of total solids.

I have been informed by the city chemist of the city of St. Louis, Dr. Teichmann, here, that one of the tributaries of the Missouri coming in at Kansas City has gone across salt beds in Kansas, and that it is very highly charged with chlorine, and that is the reason for chlorine in the Missouri river. I never made any analysis of this Kansas river.

Q. Now, if it should appear by analysis that the river from Kansas coming in from Kansas City, which I believe is called the Kaw?

A. Yes, I think that's it.

Q. That if it did not run any higher in chlorine than the waters of the Missouri river above that point, then the theory as to chlorine constituents coming from Kansas would not obtain?

A. That is so, I agree to that.

1108 In making the analyses to which I have testified here as to the condition of the water at Grafton above the mouth of the Mississippi river, I did not take into account any supposed pollution that might have been brought to the Illinois river by the entering of its tributaries.

If the waters coming into the Illinois river from the Kankakee river above the mouth of that river should contain free ammonia and albuminoid ammonia and nitrites and nitrates in pronounced quantities, they would tend to pollute the Illinois river. And so with the Fox river coming in and the Big Vermilion and other streams known to empty into the Illinois river.

1109 Q. If it should appear upon investigation and reliable data that more than half of the waters constituting the Illinois river at Grafton were contributed by streams entering that river other than the Drainage canal, and that the averages for chlorine, free ammonia, albuminoid ammonia, nitrites and nitrates, were larger or equally as large in the tributaries as in the main river, what would you say or what would be your opinion as to the amount of pollution if any contributed by the stream itself and by its tributaries?

A. In that case the proportion of these impurities which came from the tributaries would form a fraction of the impurity of the Illinois river and the magnitude of that fraction would depend upon the relative volumes of the Illinois and its tributaries and it would vary as the volumes of those tributaries vary.

In my conclusions as to the amount of pollution that is contributed to the Mississippi river at Grafton for the Illinois river, I take no account whatever of what might have come from the tributaries of the stream. I simply analyze the water as it is taken out of the mouth of the Illinois river.

Q. Then so far as your analysis is concerned, you charged up all the impurities that you found at Grafton to the Drainage canal?

A. Well, in this way, as we ascended the river we found the impurities increasing steadily and I reasoned that if the impurities came slightly from the tributaries of the river the quantities of free ammonia and albuminoid ammonia and nitrites would be pretty constant all the way up the river and up through the tributaries if the waters were homogeneous, they would show that on analysis, but we found as we ascended the Illinois river that there is a very great increase all the way up to Joliet where the analyses showed the water to be diluted sewage.

1110 The water increased in free ammonias and nitrites and in chlorine and in albuminoid ammonia. We determined the chlorine at all points. It wasn't stated in my conclusions. We didn't make a tabulated table of that but on the record or daily analysis the chlorines are given. Chlorine in potable water comes from the salt that is dissolved in the water and there is always a certain quantity present in natural water. Now if we find that a given water has a proportion of chlorine higher than this so-called normal chlorine, we at once suspect sewage contamination, for the reason that common salt is used so extensively in articles of foods and it would thus find its way with the sewage into the water.

In making my various analyses of water to which I have testified the standard of purity for drinking and domestic purposes of river water which I carried in my mind, as to chlorine was as follows: Since my analyses disclose that the Mississippi river averaged in chlorine from 4 to 5 parts per million above Grafton and since below Grafton the chlorine suddenly jumps to 15 and 16 parts per million, I conclude that that may be taken as evidence of contamination as regards chlorine, by the

Illinois river. The safe standard for the Mississippi
1111 should be four or five parts. The Missouri river, however, runs from 15 to 16 parts normally and we cannot use that standard very well with the Missouri. If the chlorine goes higher than 15 or 16 parts then it indicates contamination, but owing to the fact that the Missouri is charged with salt, from the salt beds, we are deprived from using this standard in judging of the purity of the Missouri river. We then fall back upon the nitrites and free ammonias and albuminoid ammonias.

The chlorine at the Illinois shore, Chain of Rocks, runs higher and the averages are higher than the averages for chlorine for the Mississippi river above Grafton. We find, however, that the averages for chlorine in the Illinois shore, Chain of Rocks, are very nearly identical with the averages for chlorine at Hartford, which is above the mouth of the Missouri.

Q. So it depends entirely on where the water comes from as to the potability of the water in reference to chlorine?

A. Yes, in order to use the chlorine standard we have to have the so-called normal chlorine, an idea of what the average of chlorine would be in water in an uncontaminated state. When I gave my opinion as to the potability of water coming from the Missouri at Bellefontaine and the waters coming from the Chain of Rocks, the Illinois shore, I had different standards in mind, as regards the chlorine, but not as regards the free ammonia, nitrites and albuminoid ammonia.

1112 As to nitrites, if you have nitrites that you can measure and readily represent in parts per million, it shows contamination of the water. It is the opinion of a good many writers upon the subject. There are variations, of course. And our own water is not always free from nitrites. We have measurable quantities present most of the time. The work of Prof. Mallet of the Wilmington Board of Health was done a number of years ago and he allows .0135 parts per million, although he states the average for nineteen waters that cause disease was .0403 and Leeds standard for American waters was

.003, that is the allowable amount of nitrites, the maximum amount.

1113 As to nitrates the standard which I use in making my comparisons in regard to the analyses I have made myself and to which I have testified here is five-tenths parts per million. When water comes above that it is to be regarded as suspicious. The standard for free ammonia is that when it gets above .06 it is to be regarded as non drinkable, or rather polluted, that is .06 parts per million. If it contains much higher quantities it may be used as drinking water, but it is dangerous. As to albuminoid ammonia, whenever it gets above three-tenths it is suspicious water and is unsafe.

1114 In regard to solids, I had no fixed amount in my mind as to what was regarded as safe because our solids varied so very much in the Missouri river. In high water it is so heavily charged with mud that the total solids cannot be used in judging of the purity of the water.

Q. Prof. Keiser, Saturday in your testimony you had occasion to refer to a report by Prof. J. H. Long, with reference to analyses made from water taken from the Illinois river in the year 1899, do you remember that? (See rec. 1076.)

Q. You were asked this question, "Give me the result of that, professor?"

"A. The values before the opening of the canal of free ammonia were 0.895 and after opening of the canal 3.060 according to Prof. Long, and according to my analysis 1.950."

That was above Peoria. Now I want to call attention to
1116 the fact that that is the river below Peoria and not above
Peoria at the Narrows as you compared it with.

A. Yes, I see that is Wesley. (Wesley is between Peoria and Pekin and after the sewage of the city of Peoria has been received into the Illinois river.) There is no analysis given there above Peoria, that is as near as we could come to it.

Q. Now if you will look at page 64 (of Prof. Long's report) you will see another table, that is the averages for the summer of 1900 by Prof. Long. Cast your eye along from the Peoria Narrows until you get the free ammonia—what do you find?

A. The free ammonia there in the summer is .21. And at Wesley, 1.62.

Q. You stated the value before the opening of the canal of free ammonia was .0895 and after the opening of the canal 3.060 according to Prof. Long and according to your analysis .0950. You put the comparison after the opening of the canal at 3.060. Now couldn't you have put it Peoria at the Narrows free ammonia 0.21?

A. Well, for the reason that is a further period of time.
1117 The canal was opened in January and we have our analyses that run up to November of the previous year. These first analyses come up to the end of November 1899, and then the next analyses, the nearest analyses that are published, after the opening of the canal at the point nearest Peoria, give the value I have stated in my report. The first analyses by Prof. Long were for 1899 on page 24 I think of this report. That began in July and ran until November 23. It was for the year 1899. Now, beginning with the other table for 1900, it began with June 7th and ran until October 9th. This is the one upon which .021 is based.

Q. That was based upon the analyses of water taken between June 7th and October 9th, 1900, practically the same periods in the two years.

A. Well, one is July and runs until the end of November and the other one begins in June and ends in October. There is considerable difference.

1118 What I want to call your attention to is the fact that in this statement you compare the water at Peoria before the opening of the canal, of the samples taken above the Narrows and after the opening of the canal with the samples taken below the Narrows after the Peoria sewage was in and on that basis you show a large increase in free ammonias. Isn't that right?

A. There is shown a large increase there, but the analyses come as nearly together as they have been published.

Q. Well, what I want to get into your mind if I can, is the fact that this statement here as to the difference between the conditions before the water was turned in and afterwards, was based upon two very different conditions.

A. Samples were taken at different places, I understand, but they were taken not so far apart in point of time.

Q. Well, there is a great deal of difference between the Illinois river below Peoria and above Peoria.

1121 Q. Your comparisons for this period of the conditions of the waters at the Illinois river at Peoria before the opening and after the opening of the canal, were based before the opening upon the waters above Peoria and after the opening upon the waters at Wesley, below Peoria, isn't that true?

A. I have followed the report as given here so far as Wesley is concerned.

Q. You took it at Wesley then for comparison after the canal was opened?

A. I tried to compare the points as close together as I could get them.

(Same explanation with reference to the nitrites.)

1122 (Same as to albuminoid ammonia.)

1123 Now, having called your attention to the fact that you are basing your estimate upon waters taken at different places, viz: in the first period above Peoria and in the second below Peoria, if it appears from these books that you took your second period at a place below then your conclusions wouldn't be borne out by the fact as it appears here?

A. My conclusion is borne out by the fact that I made the analyses myself of water taken above Peoria and upon those analyses showing an increase of impurities I based the conclusion that there was increased pollution after the opening of the drainage canal.

1124 Peoria Narrows is three miles above Peoria, before the sewage of the city has been received in the Illinois river. This place was called Shady Beach by Dr. Ravold.

Q. I call your attention to your testimony of Saturday in which it is stated, "Albuminoid ammonia before the opening of the canal was 0.572 by Prof. Long; after the opening of the canal, 2.210, by Prof. Long, and according to my analyses, 0.627." Now you have Prof. Long's report before you, please point out in it the page upon which you found the first figure, 0.572. That was in the year 1899.

A. This is on page 36. I took it from the line marked Peoria Narrows, 0.572. The statement from which I took the comparison of the condition after the opening of the canal I found on page 44 where the averages are given for the spring work of 1900. That was 0.221. That was as nearly after the opening as these analyses are given. That was taken from under the head of Wesley, Illinois river. And they my own determinations upon which I base the conclusions gave .627 also an increase over the original for the same period of time.

Q. Now turn to page 64 of Prof.Long's report and on 1125 the left hand column you will find Peoria Narrows, and run along until you come to albuminoid ammonia. What do you find?

A. Well, we find there .34, but I maintain that that is not a fair comparison.

Q. If you took Prof. Long's data for comparison it would show a decrease in free ammonia after the opening of the canal as compared with the period before the opening, taken from Prof. Long's statement?

A. Well, the figures that Prof. Long gives us for the summer months are lower than the figures which he gives us for 1899 for the fall months.

1126 Q. Well, is not that period covered for 1900, between

June 4th and October 1st, according to page. It is the period June 7th to October 7th, Peoria analyses?

A. Yes, sir, that is June 7th to October 9th.

Q. That is the period upon which he bases his comparison for the period after the opening? A. Yes, sir.

Q. Now the same fact will appear in reference to the findings for nitrates, free ammonia and nitrates, would it not, as far as Prof. Long's tables are concerned?

A. Yes, I have used his tables for free ammonia, nitrites and albuminoid ammonia.

Q. Then according to those two tables to which I have called your attention, Prof. Long's tables show a decrease in these items after the opening as compared with before the opening?

A. A very long time after the opening, in the summer months. I didn't know that Wesley was located below Peoria and I didn't know whether the sewage of Peoria got into the river at Wesley, I thought it was considerably below, if anything. I didn't think it was right in the town of Peoria.

1129 Well, what I desire to have you correct, if you desire to do so, is the impression which you left here, that Prof. Long's tables sustain your conclusions as to the increase of these conditions at Peoria, that is nitrites, nitrates and free ammonia and albuminoid ammonia at Peoria before and after the opening of the canal. (No answer.)

1130 Q. Having Prof. Long's tables as appear in his report, to which reference has been made, of analyses of water taken from the Narrows, above Peoria, before the opening of the canal and after the opening of the canal, don't his figures show that there was at that point a decrease in free ammonia, albuminoid ammonia, nitrates and nitrites, in the year 1900 after the opening of the canal, as compared with 1899, before the opening of the canal?

(Witness refuses to answer yes or no.)

1131 Q. In order to direct the witness' mind to the question

that I desire him to answer, I will call his attention to page 36 of Prof. Long's report. Now that contains the averages at Peoria from July 5th to November 23, 1899, is that right.
A. Yes, sir.

Q. Well, now, taking the average found for free ammonia, albuminoid ammonia and nitrites and nitrates at the Narrows, above Peoria, from samples of water taken during that period, namely, from July 5th, 1899, to November 23d, 1899, compare those averages with the averages on page 64 for the summer of 1900, taken at the same place, namely, at the Narrows at Peoria above that city, during the period from June 7th to October 9th, 1900, do they not show that for free ammonia, albuminoid ammonia, nitrites and nitrates, there was a material reduction in the latter period as compared with the former period? 1132

A. Yes, sir. We are now comparing analyses of waters made at different seasons of the year. We are comparing analyses made in the fall of the year, from July down to the end of November, when the results are apt to be low, with the analyses made in the early summer when the rivers are apt to be swollen with the rainfall, and therefore it is not a good comparison.

In my direct examination I stated that the waters of the Missouri river at Bellefontaine and the Mississippi river above the mouth of the Illinois river are both fairly good streams from a sanitary standpoint.

1133 Q. Are we to understand from that that you regard the waters of the Missouri river as suitable for the water supply of a city?

A. Yes, sir. It is not as good as it might be, but still it can be used. I stated in my direct examination that if there was an ascertainable amount of nitrites in the river water that it was to be regarded with suspicion for potable purposes.

Q. Now in your testimony Saturday you stated Bellefontaine was on the Missouri river 14 miles from the intake of the

St. Louis water works, by river, but it is above the mouth of the Missouri river. You also stated, "In order to get the idea of the condition of the water in the Missouri river during the same period, immediately before and after the opening of the Drainage canal, I have taken the average of the analyses of the Missouri river water from January, 1900, and I find that before the opening of the canal that free ammonia was 0.135, and after the opening the average for February was 0.148. The nitrites before the opening were 0.008, and after the opening 0.014. The albuminoid ammonia before the opening was 0.063, and after the opening 0.395." Now do not these conditions in the Missouri at Fort Bellefontaine show, according to the standard which you laid down this morning, that the waters at that point are not suitable for drinking purposes?

1134 A. During that period of time for which these analyses were made the nitrites ran high and the water was to be looked upon with suspicion, during the summer, however, the nitrites are very low, and sometimes you can measure them, and with that amount I say that the river is a fair stream. It is not as good as we would like to have it, but still, and during the winter months, I admit that it is to be looked upon with suspicion according to the standards that I have given. It ought to be rejected as polluted in its unfiltered state, according to the standards I gave. These conditions prevail usually during the cold season of the year, in November, December, January, February and March, along when the spring rains come the nitrites fall, and in June, July and August, they are low, sometimes we get merely a trace.

Q. Well, what would you say then of a source of water supply for a great city, that four months of the year the water was unfit for use, and they were compelled to take it always from the same place?

A. Well, I should say it ought to be filtered. Boiled anyhow, you can filter it or boil and filter too, and stop sewers from running into it.

1135 The water at the Missouri shore, Chain of Rocks, is very similar with the water at Fort Bellefontaine on the Missouri river. Of course there are variations from day to day, but taking it altogether the water at the Chain of Rocks is substantially Missouri river water.

The intake tower is about 1,500 feet from the Missouri shore.

Q. How far would that tower have to be moved inward in order to put it at a point where it would take Missouri river water only?

A. I asked that same question of the water commissioner, and at the same time asked him why he didn't take the Missouri river water, and he informed me that it was necessary to have the tower out as far as this because in dry weather the river is so low that it is impossible to get enough water for the city without having the tower out at its present position; that at low water, when the rivers got low, there is not enough water any further to the Missouri shore than the present position of the tower.

1136 Q. Then in low water, wouldn't the Missouri river be further from the shore proper?

A. At low water the water falls and the volume in the Missouri is very low, and we get much more Mississippi river water, so that it is necessary to have the tower out at least as far as it is now.

1136 RE-DIRECT EXAMINATION by Attorney General Crow:

1139 The results shown by Prof. Long of analyses made at Peoria are from weekly samples. My samples were daily samples. The daily samples enable you to get a very much better weekly average than simply taking one result. They approach very nearly the continuous condition of the stream. The daily samples are therefore to be regarded as the better for the test as to the purity of the water.

Q. Now, Judge Springer asked you a hypothetical question to the effect that if the rivers that run into the Illinois river were highly polluted, if it would not have an effect upon the pollution of that stream, and you said yes. I show you here a book called, "The Illinois State Board of Health." Turn to page 64, examine that and see if it is Prof. Long's report.

A. Yes, sir, it is Prof. Long's report as to the condition

1140 of the Illinois and some of its tributaries. That report is from June to October, 1900. The analyses show that the Illinois river is very much more polluted than any of its tributaries, and at low stages of course, less water would flow in.

1141 I have here a preliminary report to the State Board of Health by Prof. Rauch, M. D., Secretary. There are two appendices, one, chemical investigation of water supply of the Illinois, by Prof. J. H. Long and the other Illinois Basin and its relation to sanitary engineering, by L. E. Cooley, civil engineer. Turning to page 15, I find that Prof. Long, in a note paged to table 7 states:

"From table 7, it will be seen that the amount of organic matter in this water as indicated by albuminoid ammonia and oxygen consumption, is quite large, and as both are undoubtedly chiefly of vegetable origin, its effect should not be lost sight of." This refers to the table giving the physical conditions and constituents of the Kankakee river. I will ask you to examine that table and see if it bears out the statement that Prof. Long makes.

MR. JOHNS: Objected to as not re-examination.

A. Compared with the values for the Illinois river, there is very much smaller free ammonia and albuminoid ammonias. For instance they only run up to .1—free ammonia .1, and the Illinois river running much higher.

Q. I show you here a report of the Illinois State Board of Health: Advance notes of the Sanitary Investigation of the Illinios river and its tributaries, Springfield, Illinois, 1900, with special reference to the effect of sewage of Chicago on the

DesPlaines and Illinois river prior to and after the opening of the Chicago Drainage canal. On page 34 we find a table of averages of chemical constituents of the waters of the canal at Bridgeport, Lockport, Joliet, Wilmington and then Illinois river at Ottawa, Peoria and the different streams that
1142 come into the Illinois. I will ask you to take that, examine it and say if you can determine from that table whether or not the tributaries there are less polluted as shown by the nitrites, free ammonia and nitrates they carry, than that of the Illinois river.

MR. JOHNS: Objected to for same reason.

A. The nitrites run very much lower. The free ammonias are also very much lower than of the Illinois river. This holds for Wilmington, and for Ottawa, on the Fox river, and for Havana on the Spoon river, and for Brownings. The free ammonias and the nitrites, and the chlorines are all very much lower in these tributaries than they are in the Illinois.

If most of the drainage from the tributaries of the Illinois, into the Illinois, were what we would call the rural character that would be different in its effects on the water than if there came into those streams and tributaries sewage flowing through sewers from larger cities and towns. We would find high chlorine, for instance. Now we do find low chlorines in these tributaries that flow into the Illinois, and we also find low ammonia—free ammonia, whereas in the Illinois itself there
1143 is a higher free ammonia, and similarly with the nitrites in the tributaries—they are low. This indicates that the organic matter is of vegetable source when we have low chlorines and low nitrates, whereas when the chlorines are high, and the free ammonia is high and the nitrites high, those three things together indicate animal sewage.

Q. Now, Professor, Mr. Johns asked you the question as to whether or not your analysis made to determine the quantity of Mississippi and Missouri river water that came into the intake of the St. Louis waterworks was an actual measurement, scientifically made, of the amount of water of the two respective streams, the Missouri and the Mississippi, that came into the intake of the waterworks at that point, and I will get you to state now, whether or not it was such a scientific measurement.

A. It was a scientific measurement, calculated from the measured quantities of nitrites in the water. It is the usual and ordinary method that water chemists use for the purpose of determining the relative amounts of two streams, whose waters have commingled at a given point. That analysis made by me determined chemically the amount of those waters. It was made for the purpose of tracing these impurities that I found in our reservoir water, to their origin. A chemical analysis of water does not constitute the measurement of the volume of the flow of the water, or body.

1144 The analyses made by me determined the quantity of pollution as contributed by the two streams. The chemist is able to determine that from this method of water analysis.

Q. Suppose where the Missouri and the Mississippi come together the water of the Missouri was about 1-3 greater than that of the Mississippi—but the Mississippi was polluted twice as great as the Missouri at the point of confluence. Then would the amount of pollution found by water analyses below the junction of the streams correspond necessarily with the relative volumes of the two streams at the point of confluence?

A. No, sir. It would show rather than the volume of the streams it would show us the proportion of impurity which came from each of the streams. That is the value of the analytical determination of the commingling waters of the two

1145 streams. I do not consider the water commingling of the Missouri and Mississippi, as it comes into the intake of the St. Louis waterworks, since the opening of the canal, is a safe, sanitary water for the use of cities of this size. The water that I drink at my house is all boiled and filtered.

1147 **RE-CROSS EXAMINATION** by Judge Springer:

I sometimes drink water when it has been run through a

Pasteur filter. A Pasteur filter would remove the larger proportion of the bacteria from the river water, without boiling, I believe.

Q. Are there any waters in the navigable rivers of the United States that you would recommend people to use without being filtered and boiled, for drinking purposes?

1148 A. Well, I imagine there are some rivers. The upper Missouri is probably in a very good state, and it is navigable I believe for many thousand miles. I believe the Missouri above Kansas City and St. Joseph is a very fair stream and that it could be used as a potable water. I think all of our river waste waters ought to be filtered. There is danger of contamination from any of them unless they are filtered.

WILLIAM C. TEICHMANN, resumed the stand for further direct examination by Attorney General Crow and testified as follows:

States his professional training, and methods pursued in the chemical analyses of the waters under consideration in this hearing.

1154 I suggested to the city authorities that Prof. Keiser be engaged for duplicate work. The work he did corresponded with the work I did, in quantity. I did duplicate work the same as he did. I superintended the analyses of duplicate samples with the samples that Prof. Keiser received in my laboratory.

1163 In order to get the proper weight of the sources of pollution which affect the sanitary character of the Illinois river we will have to consider some figures from responsible authorities on the effect of dilution from the Illinois & Michigan canal and the tributaries.

Since it is of the greatest importance to find out the stages of the river during the periods of drouth, we will look for the low water stages of the Illinois river water shed. Perhaps the lowest on record is that discussed from the U. S. Government data by Lyman E. Cooley in a report published in 1890, entitled

"Lakes and Gulf Waterways as relating to the Chicago Sanitary Problem."

Witness quotes from this work, and adds.

1164 MR. JOHNS: I object to reading from books. If the evidence is competent the books themselves are the best evidence.

From Lyman Cooley's remark we may assume for the purposes of calculation, that the natural low water volume independent of Chicago sewage, above Havana is 300 cubic feet per second and below this point is 8 cubic feet per second. Now this is the condition prior to the opening of the Drainage canal.

1165 From those figures I have calculated the following ratio of dilution of Chicago sewage in the Illinois river prior to the opening of the Drainage canal.

Upper Illinois volume of flow 600 cubic feet per second, as established by Cooley and Harman.

Sewage of Chicago, 400 cubic feet per second, ratio of dilution, 1.05.

Lower Illinois: volume of flow, 1,200 cubic feet per second, that is the upper district runs to Utica and the lower district from Utica to the mouth. That is, the lower Illinois had a volume of flow of 1,200 cubic feet per second and the sewage of Chicago 400 cubic feet per second, making the ratio of dilution one to two. I deducted the sewage from the water.

1166 Now for instance, 600 cubic feet of water I have there and I have 400 cubic feet of sewage, that leaves 20 per cent. 200 to 400 equals 0.5 as the ratio of dilution. In the same way we would refer to the 1,200 cubic feet of volume per second in the lower Illinois and sewage 400. Deduct that 400 from 1,200 and it leaves 800 and 400 is to 800 as is one to two.

Amount of sewage from Chicago was obtained by taking it equal to the water supply of 42,000.00 cubic feet per day. We have thus deducted 400 cubic feet per second as the amount of sewage discharged there prior to the opening of the Drainage canal.

Of course these dilutions are given only to show just what proportion of the Illinois river is made up as the diluted sewage of Chicago and the purification of this sewage must be taken seriously into account before arriving at definite conclusions.

1174 I have no data for my own analytical work of the condition of the Illinois river in 1899, but have consulted the following reports.

Water Supplies of Illinois, published by Rauch.

Long's Chemical Investigations of the Water Supplies of Illinois.

Palmer's Chemical Survey of the Water Supplies of Illinois, etc.

I have here some tables quoted from these reports in their comparison lead to the following deductions, first:

That the Illinois river prior to the opening of the Drainage canal was being constantly polluted by the I. & M. Canal and to such an extent as to give the entire water course the character of a carrier of diluted sewage, showing that the dilution of sewage for the lower Illinois river between Utica and the mouth at times of draught was one to two.

1175 It is true that dilution, sedimentation and oxidation gradually lessen the quantity of characteristic ingredients of sewage present, but not sufficiently by the time the Illinois reaches its mouth to have completed the process of self purification. All the tributaries entering the Illinois river are comparatively much purer than the Illinois itself. That is a conclusion that I draw from these reports.

These are all conditions previous to the opening of the Drainage canal.

The second conclusion that I draw is that there was a remarkable increase in the sewage pollution as evidenced by the higher nitrites, chlorine and free ammonia in the river since Long has examined it in 1888, and again since Palmer's investigation.

This pollution cannot be ascribed to accessions from the tributaries or from the Peoria and Pekin pollution for the reason that during the same period those tributaries show no increase in pollution.

1176 It is only necessary to consider the corresponding increase of water in the Illinois & Michigan canal during this period of 1888, 1896 and 1900 and to remember the enormous growth of population and industries in Chicago to find the right explanation of the gradual conversion of the Illinois river at that time into a condition of very bad pollution.

Prof. Palmer states that "the I. & M. canal and Illinois river were during the fall of 1895 and year of 1896 much more fully charged with sewage than they were in 1888 and 1889," the time of the investigations made by Long under the Board of Health.

As to examinations made prior to opening of canal, from August 23 to January 22, at mouth of Illinois above Grafton and from the Mississippi above Grafton, I have presented a table of maximum, minimum and average results.

(Table No. 1, Teichmann's testimony.)

1178 From the original date it will be seen the nitrites, free ammonia and chlorines of the Illinois river were found to exceed those of the Mississippi.

On September 30, for instance, a sample from the Illinois river contained 31 parts of chlorine per million; 44 parts of ammonia per million, and .015 parts of nitrogen in the form of nitrites.

Whereas in the Mississippi we find, 5 parts of chlorine per million; .134 parts per million of nitrogen in the form of free ammonia; and .002 parts per million of nitrogen in the form of nitrites.

It is true that the highest albuminoid ammonia in the Mississippi river was on the same day found to be higher in the former than in the Illinois river, but it was not accompanied by correspondingly higher nitrites and chlorines. Therefore the conclusion is justified that the sanitary character of the Mississippi river at that time was better than the Illinois river.

1179 We next come to the chemical character of the Mississippi river water between Grafton and the intake of the St. Louis water works in 1899.

There was no doubt of the polluting effect of the Illinois river on the Mississippi.

1180 Analyses of the water of the intake, in 1889. From August 23 to September 16, 1899, four samples were collected near the intake of the water works, but beginning with October 16 and ending January 22, 1900, semi-weekly analyses were made at the intake. The averages of the most important chemical constituents were as follows:

Table of averages, parts per million: Nitrogen as free ammonia, maximum, .138; minimum, .008; average, .0063.

That is the whole of the period at the intake. I will give the number of samples, 26 samples.

Nitrogen as nitrites, maximum, .01; minimum, .0; average, .002.

Nitrogen as nitrates, maximum, .8; minimum, .2; average, .4.

1181 Nitrogen as chlorine, maximum, .27; minimum, .9; average, .17.

The maximum stamps the water as polluted, whereas the minimum characterizes it as good potable drinking water.

These great fluctuations can only be ascribed to the daily varying mixtures of Mississippi and Missouri river waters at the intake which is located on the edge of the channel 1,500 feet from the Missouri shore.

The Missouri river showed much lower nitrites and free ammonias than the Mississippi above the mouth of the Missouri at that time. When the Missouri would go into the intake the impurities in the water at the intake would be low. When the Mississippi river prevailed, the impurities in the intake would go up.

1182 Now as to the final conclusions on the work of 1899, the Illinois river at its mouth was badly polluted during the entire period. The Mississippi river above the mouth of the Illinois, was much better in sanitary quality than the Illinois throughout the investigation.

The Mississippi river between Grafton and the St. Louis intake showed very much the effects of pollution from the Illinois river and on such days when the Mississippi river water entered the intake, the result would be an increased pollution of our water supply.

The Missouri river was generally purer than the Illinois above Grafton and purer than the Mississippi after its junction with the Illinois river.

The next period of the investigation covers the time from January 23d until October 11, 1900.

Witness states that 3,492 samples were taken and enumerates the various points and the number of samples at each point.

1183 After October 12, weekly samples were collected from the following points until November 30th. (Naming them.)

The sources of pollution in the Illinois river are the sewage of Chicago, the sewage from the towns along the banks of the DesPlaines and Illinois river and from the tributaries. Particularly a large percentage as I have already said, according to the statement of E. O. Jordan, a large percentage of the sewage from Chicago came by way of the I. & M. canal. I wish to emphasize that this is the opinion of Prof. Jordan. Much of the Chicago sewage to-day passes through the main branch of the canal.

1185 The sewage passing or mixing with the lake water in the Chicago river, south branch and entering the Drainage canal, that sewage represents the drainage of a population less than 800,000. That is the sewage that enters the main branch of the canal.

The sewage entering the I. & M. canal, according to my observations and the testimony of Mr. Benezette Williams, comes from the south fork of the south branch.

The sewage that enters the south branch is of a different

character than the sewage in the south fork of the south
1186 branch of the Chicago river. There being no current in the south fork it is kept there for a sufficient time to enable it to undergo preliminary purification. This is not the case with the sewage entering the south branch directly that is draining from the population of 791,677. The south fork may be compared to a septic tank.

Now it has been proven that water when it stagnates facilitates to a great extent, purification much more so than that of running streams. In septic tanks the most effective are always
the obligatory anaerobic bacteria. The Chicago Drain-
1188 age canal contains dissolved oxygen. The lake water provides it. There is also dissolved oxygen in the south branch today. The north branch ordinarily is also a septic tank. This is an advantage to the water as it leaves the Drainage canal and enters the Des Plaines and Illinois rivers.
1190 The conduits testified to by Mr. Williams will change this condition and push the sewage right out into the south branch and will prevent its purification while in a stagnant condition in the north branch and south fork of the south branch.

In a measure it is already being done by the so-called Fullerton avenue conduit, whenever that is in operation, but it will be done still more by the Lawrence avenue conduit and the 39th street conduit now in course of construction. This will then carry all the remaining sewage of the city of Chicago through those conduits directly from the Chicago river into the Drainage canal, excepting that part of the sewage, of course, still being dumped into the Illinois and Michigan canal whenever in operation. There will still remain the sewage of the district of Calumet and the district of Evanston, representing in toto a population of about 100,000. They will still drain into Lake Michigan. The remaining sewage will all be discharged into the Drainage canal at the rate of flow fixed by the United States War Department at 250,000 cubic feet per minute.
1193 In all problems dealing with the sewage disposal by

method of discharge of crude sewage in streams, there are two important problems to be considered:

First, the oxidation or mineralization of the organic matter in sewage with subsequent absorption of final products by plant life.

Second, the destruction of pathogenic or disease producing bacteria.

The prime factor which affects the capacity of the streams to accomplish the results as outlined above, are the volume of sewage discharged into it, the degree of dilution of the same, the volume and velocity of the stream, the length of the stream, and finally the character of its water—the chemical and bacteriological character of its water.

1192 The flow of water in the canal is about 1.92 miles per hour in the rock section, and 1.26 miles per hour in the earth.

1193 Taking Prof. Jordan's figures, the ratio of dilution of Chicago sewage in the Drainage canal is one to nine.

These figures should be modified. Less than 800,000 population of the city of Chicago drain directly into the Chicago river, and the south branch and mixes directly with the 250,000 cubic feet of lake water running through the Drainage canal, per minute. Now this sewage, as I said this morning, is running to the Drainage canal, and mixes with the water and is really the only sewage from Chicago, from which a normal calculation should be based as to the ratio of dilution. This ratio of pollution based upon the population of say 800,000 would make a ratio of dilution from one to about twenty-one.

The rest of the sewage from the other 900,000 population drains partly into the north branch of the Chicago river and partly into the south fork of the south branch of the river, and partly, according to the estimates of Engineer Williams, into the lake, the latter representing the drainage of 300,000 into the waters of the lake.

1194 Q. Don't the waters of the north branch of the Chicago river run into the south branch? A. Yes, sir.

Q. And thence into the canal?

A. Whenever storm water and heavy rains flush out the north branch and the south fork much of this sewage which has largely undergone an advanced stage of preliminary purification, is rushed with recent accessions of fresh sewage into the Drainage canal. Eventually it all goes in, but I drew the distinction this morning between the sewage previously decomposed and in the preliminary stage of purification by the anaerobic bacteria and fresh sewages.

I will demonstrate from my data, whenever an increased amount of sewage was run into the Drainage canal during my investigation, the impurities at Lockport would increase. In fact there is shown an increase all along the line up to the mouth of the Illinois.

So that in time of rain, when these streams are high, it all goes in the Drainage canal except the sewage from about 300,000.

1196 ATTORNEY GENERAL HAMLIN: I object to testimony collected from reports and hearsay.

1197 Chemical examination of the water from Lake Michigan in the harbor of Chicago. 32 samples were collected during this period of July 23d to November 17th, 1900, from Lake Michigan, at various distances of from two to ten miles from Chicago.

Since the opening of the Drainage canal the condition of the lake water has improved materially. This is shown by average results of our analyses as compared with those performed by other investigators in previous years.

We found an average of the 32 samples of water collected
1198 from July to November, 1900, of free ammonia, .045 parts per million; nitrogen as nitrites, .15; chlorines, .6.

These averages would probably be still lower were it not for the fact that during September on certain days the Chicago river again flowed into the lake because of the temporary closing of the gates at Lockport, and this resulted in a re-pollution of the water on the lake front, and the sample taken near Lake

View crib, December 7th, contained .086 parts per million nitrogen as free ammonia; .014 parts per million, nitrogen as nitrites; .2 parts per million of nitrogen as nitrates; six parts per million of chlorine.

1200 During the last ten years the discharge from the pumps at Bridgeport in the I. & M. canal was practically crude sewage, after having partly been disintegrated by anaerobic action in the Chicago river and in the south fork and north branch.

The analyses of samples of the contents of the canal showed an entire absence of absorption of oxygen, without which practically no oxidation can take place. In other words you have here in the I. & M. canal a septic tank.

1201 These conclusions are largely confirmed by Prof. Long's analyses of 1899, by whom 27 weekly samples were taken between July 1 and November 27, 1899, with the following results:

At Bridgeport nitrites were absent, or present only in immeasurably small quantities or amounts, for all but three of these weeks. Twice they were as high as 01. and once reached .64 parts per millions.

At Lockport almost identically the same conditions were found. The nitrates at Bridgeport were uniform—absent with but one exception. That was before the opening of the Drainage canal.

1203 Results of examination at Joliet, in Des Plaines river: free ammonia, maximum 8.284; minimum 1. 246; average, 2.759.

Rudolph Herring says that when free ammonia is greater than 1.2 per millions, the conditions are probably objec-
1204 tionable. This represents chart 1, describing in curves the comparison between weekly averages of results of analyses of daily samples collected at Lockport, from the Drainage canal, collected at Joliet after mixture of the Drainage canal, and the Des Plaines river, and also respecting the mixture of the Illinois & Michigan canal. The samples were taken

at McDonough street in Joliet and three miles above Peoria. That is the curves will show fluctuations at Lockport and Joliet and that they produce similar fluctuations at Peoria to show that there is little change and practically no material improvement in the Chicago sewage in traveling from the lake front to Lockport.

1205 You see here (indicating on map) a rise in the Drainage canal in free ammonia is followed by a rise of free ammonia in the river at Joliet and is followed by a rise of free ammonia at Peoria, and you will find here the amounts of free ammonia all figured out. Of course the crossing of the DesPlaines river at Joliet by the I. & M. canal—the canal causes a large acquisition of the sewage there from the Illinois & Michigan canal, and that must be taken into account in reviewing this chart. That is what brings those high free ammonias, as I said before, at Joliet, and also brings the high chlorine up there at Joliet, running as high as 32 parts per million of free ammonia; here as high as 54 per million, but you will notice the fluctuations correspond pretty much.

1206 I have a table of average results of daily analyses for the period from January 23 to October 11, 1900, and I have also a table containing the maximum, minimum and average results of analyses from January 23, to October 11, for the same year, 1900.

1207 This would show for the Bear Trap dam free ammonia on September 18, the highest amount of free ammonia was reached at Bear Trap dam, at Lockport, 4.8 parts per million.

Minimum May 18th, .706 parts per millions, making average of 1.585 which is represented on this map here.

Nitrites, maximum also at Bear Trap dam, .2 parts per million; minimum, zero; average, .026.

This is chart No. 2. The red line shows Illinois river; three miles above Grafton. The blue line represents the Illinois river three miles above Peoria.

The curves represent the graphical condition of the Illinois river at Grafton, and Peoria during January and February, 1900, prior to and immediately after the opening of the Drainage canal, January 17.

These results clearly show the enormous pollution caused by the flushing out of the Chicago river and the Drainage canal, and that owing to the excessive quantities of organic matter present, self-purification was practically impossible. The amounts of free ammonia, chlorine and nitrates represented the effects produced, and although the incomplete purification is also demonstrated by the other results of the organic matter the principal object of this chart is to make a comparison of the results at Peoria and at Grafton during the months of January and February, 1900. It will be noticed that in January, immediately after the opening of the canal, the chlorine go up from 21 parts per million to 28 at Peoria. This is follow-
1208 ed by an increase at Grafton from 15 to 23 parts per mil-
lions. It will be seen that the chlorines go pretty much together in the fluctuations at Peoria, as well as Grafton.

As regards free ammonia, we notice the same conditions Illinois river three miles above Grafton as we do three miles above Peoria. The fluctuations correspond between Peoria and Grafton, making allowance for the flow of the water.

This is chart number 3. We find here the results at Grafton and Peoria again campared by covering a period from January until October, 1900.

1209 The top line indicates free ammonias. We again see the corresponding fluctuations in the free ammonias at Grafton and Peoria, particularly during the early parts of the year.

As regards the nitrites, we notice a significant correspondence of the fluctuations in nitrites results for the two points during the first two months, but during the summer months, the warmer weather facilitating the action of the aerobic bacteria in the Illinois river, we find much of those nitrites oxidized eventually because the fluctuations are not so high any more during those summer months for Grafton as they are at Peoria.

Chart number 4 shows the results of the waters analyzed from the mouth of the Illinois several miles above the mouth of the Illinois in the Illinois and several miles above the mouth of the Illinois in the Mississippi. They show above all, the peculiar unstability of the Illinois at Grafton as compared with the Mississippi, a much more stable river as far as its pollution is concerned, and as far as fermentative action itself takes
1210 place.

I have also here the river stages for the two rivers.

1211 My conclusion is that the Illinois river was very much more impure than the Mississippi above the mouth of the Illinois during the year 1900, and was evidently in a badly polluted condition.

1212 I have already stated that the Chicago sewage is only partly purified by the time it reaches Peoria, as was shown on the chart by the high free ammonia, high nitrites and the high chlorines coming together, we must certainly admit a large amount of nitrification and oxidation between Lockport and Peoria, but it is in no sense sufficient to render the Illinois river potable by the time it reaches Peoria.

The water above Peoria, as determined by analytical examinations shows that it is polluted.

I have already quoted Prof. Drown as having stated that high free ammonia, with high nitrites and high chlorines together, establish water as sewage polluted.

Now regarding Peoria sewage. Population of Peoria is 56,000. We figure on 150 gallons of sewage per inhabitant. On this basis we take 8,415,000 or 1, 222,000 cubic feet
1213 of sewage per 24 hours running into the Illinois river from the city of Peoria. That is, if we take the total population. But from recent data I have learned that the sewage draining from the city of Peoria into the Illinois river would represent only 47 per cent of the population. The rest of it goes into privy vaults and is lost in the ground.

Minimum flow of the Illinois river at Peoria prior to opening of Drainage canal, according to Cooley, was 72,000 cubic feet per minute. If we add to this the discharge from the canal of 250,000 cubic feet per minute, we have a minimum flow of the Illinois at Peoria of 322,000 cubic feet per minute. Now we take the above value of 1,122,000 cubic feet per 24 hours or 779 cubic feet per minute, and we will find that the dilution of the Peoria sewage at a low river stage as was recorded by Government data and presented in Cooley's report, and taking in the whole population, which as I say I have recently discovered is not the case, we find a ratio of dilution of the Peoria sewage in the Illinois river of 1 to 413, at the lowest stage of the river.

In other words, if we take the sewage of Peoria and run it into water at such a ratio of dilution, the sewage would, in my opinion, after a run of from 25 to 50 miles, be sufficiently purified with so much water added to the sewage, so as to remove the effect, the polluting effect of the Peoria sewage on that river.

1214 The sewage of Peoria adds to the pollution of the Illinois river, but only to an extent that if the Illinois river were pure, that would be what I call a comparatively pure water, because absolutely pure water is only distilled water which you find in the laboratory, but I mean to say an ordinary good river water, potable—I will say that if it were a potable water before it came to Peoria, that the sewage entering the Illinois from Peoria would, after running from 25 to 50 miles, purify itself so as to remove the polluting effect of the Peoria sewage on the Illinois river.

Q. You mean by that chemically or bacteriologically?

ATTORNEY GENERAL HAMLIN: Objected to as not being proper; the answer doesn't require any explanation.

A. Chemically, yes.

Q. Do you mean that that would also be bacteriologically purified?

A. Well, that would involve a consideration of the bacterial action of facultative anaerobic bacteria and aerobic bacteria. 1215

Q. Well, go ahead.

A. That is, would certainly have finished the purifying process after having run the distance that I have mentioned.

In conclusion I wish to say that the Illinois river as a whole, furnishes a good example of the inability of an excessively polluted stream, excessively polluted at the point where the Des Plaines river enters it, shows the inability of an excessively polluted stream to recover itself.

It is seen that the ability of such a stream to purify itself is dependent on the amount of sewage added, and the volume of water coming down the river, and the results at Grafton plainly show that the Illinois river is at times overloaded with sewage, and literally fails in this capacity of recovering itself or of purifying itself.

Chart number 5 shows:

Sanitary condition of the Mississippi river between Grafton, Illinois and St. Louis.

Red line represents the Illinois river three miles above Grafton.

1216 Blue line represents the Mississippi river one mile above Grafton and yellow line represents the Mississippi river at Hartford and brown line represents the Mississippi river at Alton.

This represents 1900 from January 23d until October 12th.

It will be seen that during the months of January and February there was a marked pollution of the Illinois river water at Grafton.

1217 It is again demonstrated by the results as shown here for nitrites during 1900, that high nitrites at Grafton in the Illinois river were always followed by an increase in nitrites at Alton and Hartford.

That indicates that the Illinois river effectually pollutes the Mississippi after joining it at Grafton.

I have here chart No. 6 showing a comparison of the Missouri river water taken from Bellefontaine, Missouri, and the water taken from the Missouri shore at Chain of Rocks from January 23, to October 12, 1900.

1218 It shows clearly that the water coming down the Mississippi river along the Missouri shore as it passes St. Louis, is principally consisting of Missouri river water. You have here the red line representing the Missouri river at Bellefontaine and the dark line representing the Missouri shore at Chain of Rocks. It will be seen how the chlorines run together, very close together and it will be seen from the total solids that they are almost identical, almost alike.

Whenever the Missouri river is high and is flushed out or storm water comes down the river, there is a marked stirring up of the river and the increased sedimentation produces very high total solids or residue on evaporation. This can be seen if you look at the chart for February and March and April where the amount of solids estimated in parts per million, rose from 800 on February 27 to 3,750 parts per million of total residue was found then in both waters, the waters of the Missouri at Bellefontaine as well as the Missouri river at the Chain of Rocks, and the subsequent remarkable drop back again to about 1,200 in the latter part of March, again shows how closely those waters resemble each other, the waters of the Missouri river at Bellefontaine and the water on the Missouri shore.

Chart No. 8 represents a cross-section of the Chain of Rocks, St. Louis where the intake of the St. Louis water works is located.

1219 This covers from January 23 to October 12, 1900.

It shows there are more solids in the water after evaporation, from the Illinois shore than the Missouri shore.

1220 I have a table which I shall present. It shows that the intake tower invariably has higher total solids than the Illinois shore except on the occasion here shown on the map in March when they come very close together, and the Missouri shore has, of course, always higher total solids except on the occasion there where the mixtures result in slightly higher total solids at the intake.

The conclusion is this, that since the results at the intake and the Missouri shore differ as a rule, although they come close together some times as is shown in August, 1900, that there must be a mixture of the water running along the Illinois shore and of the water running along the Missouri shore, at the intake tower.

1223 In discussing the results of the analyses of samples taken in 1900 from January 23 until October 11, from the Mississippi river between Grafton and the intake, I wish to call attention to the excessive pollution of the Mississippi river during the months of February and March as resulting from the excessive pollution of the Illinois river.

I will just take a week beginning January 30, 1900, and take the averages of the results for this week. The average free ammonia in the Illinois river at Grafton for the week bginning January 30, 1900, the nitrogen in the form of free ammonia found in the Illinois a few miles above Grafton amounted to 1.675 parts per million, while in the Mississippi river, a few miles above the mouth of the Illinois, the corresponding average amounted to .175. That is only one-tenth of the free ammonia was found in the Mississippi above the mouth of the Illinois than was found in the Illinois at Grafton.

At Alton and Hartford we find 1.055 and .865 parts per million respectively, so that we see here from the figures a remarkable increase in free ammonia at Hartford and Alton after the two rivers had mixed.

1224 The Missouri river is noted for its great variations in amount of suspended matter it carries, which variations are most noticeable at the times of freshets, when it may contain as much as 4,000 parts per million of suspended clay and silt.

Another characteristic feature of this water is its high chlorine contents. This is due to the drainage of the Kaw river through large districts in Kansas of salt deposits. The Kaw is a tributary of the Missouri.

A very important point as regards the Missouri is the condition of the banks which owing to enormous corroding action of the current steadily washing many portions of the soil, particularly the case when it approaches its mouth.

1225 The soil that is washed by the freshets into the Missouri river carries an abundance of organic matter contained in this soil, of vegetable origin principally. If the high albumonis ammonias that are found in the Missouri river were due to sewage contamination they would be accompanied by high nitrites and high chlorines. NOW I HAVE DEMONSTRATED THAT HIGH CHLORINES IN THE MISSOURI BETWEEN KANSAS CITY AND ST. LOUIS ARE NOT OF SEWAGE ORIGN, ARE OF SALT DRAINAGE ORIGIN IN KANSAS, BECAUSE THE MISSOURI RIVER ABOVE KANSAS CITY SHOWS COMPARATIVELY LOW CHLORINES.

The nitrites in the Missouri throughout the year are low. They are frequently absent. The fact that they are low and absent and that the variations between the highest nitrites found and at times when they are absent, the variations being very small, show that there is a very little fermentative action going on in the Missouri river, particularly as it approaches its mouth. We are justified in stating that the general character of the Missouri river as it approaches the mouth is one of great stability.

These tables that I refer to show that all the times during this investigation, the second period from January 23 until October 12, 1900, the Missouri river water was better in its sanitary quality than the Mississippi river water at the mouth of the Missouri river. While the averages may show free ammonias quite high in the Missouri river, the averages for the nitrites show much lower results for the Missouri than for the Mississippi at the mouth of the Missouri. That would stamp the Mississippi as being a more polluted stream than the Missouri. And since the chlorines, nitrites and free ammonia in the Mississippi at Hartford and Alton, Hartford being situated one mile above the mouth of the Missouri I say since those results from those points of collection at Alton and Hartford show correspondingly high nitrites, free ammonias and chlorines, that the pollution of the Mississippi at these points must be principally of sewage origin.

I have here a table of percentage calculations of which I spoke in discussing the charts of the Missouri and Mississippi river water at the intake, a mixture as represented by the analytical results, of total solid determination.

The tables offered are 1, 2, 3, 4 and 5 of Dr. Teichmann's testimony of March 18, 1903. (See rec. 1227.)

1240 Chart number 9 represents a comparison of the percentage of the Mississippi river water pumped at the intake as represented by the determination of total solids or residue on evaporation, from January 23 until October 10, partly and October 30, for the typhoid fever cases.

1241 The percentage of Mississippi river water pumped at the intake during this period as compared with the number of typhoid fever cases for the years representing 1895 until 1899 inclusive.

It will be seen from this chart that during February from February 15 to 25, a marked increase of Mississippi river water in distinction from the percentage of Missouri river water was pumped into the intake. There then followed, taking into account a period of incubation of two to three weeks, a remarkable increase in number of typhoid fever cases reported to the health department of St. Louis.

I also show here in blue the normal number of cases, reported to the health department for 1895, 1896, 1897, 1898 and 1899. They show a very low number of cases during that period and the increase in the number of typhoid fever cases reported in March, 1900, over the period found for the five preceding years amounts to 1,300 percent.

1242 We notice during the latter part of the summer again an increase of percentage of Missouri river water entering the intake and we see subsequently a large increase in the number of typhoid fever cases reported to the health department over the average of the five preceding years. In September, 1900, the increase in the number of typhoid fever cases reported over the period of the five preceding years amounted to nearly 70 per cent.

Chart number ten represents a comparison of the water at the intake, the water after it has been in the reservoir for two days and just before it leaves the reservoir.

Between the reservoir and the tap in the city chemist's office and the intake.

The blue line represents the intake, the yellow line the reservoir and the red line the tap and the top line represents the stage of the Mississippi river at St. Louis and the number of feet are marked up here in lead pencil. They simply show the enormous removal of suspended matter in the subsiding reservoir; the average percentage of removal of suspended matter in the reservoirs for the period of 1900 from January 23 until October 12 represents 85 per cent. That is 85 per cent of the sediment of the water passing through the reservoirs remains in the reservoirs.

Increased pollution of the water entering the intake is always followed by increased pollution of the water in the reservoir. As a rule there is no marked purification as far as the free ammonia is concerned in the reservoir. Whenever the intake water is bad the water leaving the reservoir and the water from the hydrants in St. Louis must be correspondingly affected.

The same applies to nitrites.

Now I wish to call attention to a marked increase in pollution of the water at the intake during the early part of 1900. You will see that there is a tremendous rise in the free ammonia and you will see a tremendous rise in nitrites. The ammonia lines and the nitrite lines indicate this on the map.

1244 There are analyses on record for the last twenty years. None of these ever showed such a remarkable quantity of free ammonia and corresponding with it a large increase in nitrites at the intake tower or the reservoir or the water of the hydrants of St. Louis. At that time (early in 1900) there was a wave of pollution coming down the Des Plaines river, the

Illinois river entering the Mississippi at Grafton running along the Illinois shore opposite the St. Louis waterworks at Chain of Rocks, and as shown by the percentage mixture, entering the intake of the waterworks. We find during that period the percertage of Mississippi river water entering the intake varying from 19 to 100 per cent during this early period of 1900. After the opening of the canal.

1245 Generally comparing the results of the analyses of waters collected between Grafton, Illinois river and the Mississippi river and the St. Louis intake, and also from the Misrousi river and the St. Louis intake, and also from the Missouri river for the periods of 1899 and 1900, we notice from the averages an increase in the nitrites and free ammonia in 1900 as compared with 1899, for the route between Grafton and the St. Louis intake. Our analytical results show that the water entering the intake in 1900 was more polluted than the water entering the intake in 1899, and that the increased pollution, since there was no correspondingly increased pollution in the Mississippi river above the mouth of the Illinois, nor was there increased pollution in the Missouri river above its mouth, it shows that the increased pollution of the water going into the intake tower must be ascribed to the increased pollution of the Illinois river in 1900, and since I have shown that the increased pollution of the Illinois river at Grafton was due to the increased pollution of the DesPlaines river following the opening of the Drainage canal, I feel justified in declaring that the opening of the Drainage canal resulted in increased pollution of our water supply.

1246 After the investigation closed in October, 1900, a number of samples were still collected between October 12 and November 30, from points in the Illinois river, and these samples were promptly analyzed at the city chemist's office. These samples were not collected daily as before.

For the samples taken outside St. Louis they covered the period from October 12 to November 30.

But from October 12 to November 30, 1901, the third period of investigation, covered in addition to those sporadic samples outside of St. Louis, they covered the analyses of samples collected daily at the Chain of Rocks.

1247 Sample was daily taken during this period at the Chain of Rocks from the Mississippi river close to the Illinois shore. Then a sample close to the Missouri shore. Also from the water right at the entrance of the intake tower, and on from the outlet chamber. And one from the tap in the city chemist's office.

The analytical data thus collected have all been noted down in the report which can be presented if required. They demonstrate the continued polluted character of the St. Louis water supply during this period. Furthermore, that the water along the Illinois shore during this period was at all times more polluted than the water running along the Missouri shore and that during such periods when a mixture of the waters from those two rivers entered the intake, the impurities found in the samples from the intake were higher than those found in the samples from the Missouri shore.

The next or fourth period of investigation, covers the time from October 1, 1901, to November 30, 1901. It was the most comprehensive investigation conducted since the beginning of the analytical survey of these waters in August 1899.

1248 Samples were collected at Bridgeport, Lockport, Bear Trap dam, etc.

1250 First period of investigation was from August 23, 1899, to January 22d, 1900;

Second period, from January 23d until October 12, 1900; and a number of samples were still taken between October 12, until November 30, 1900;

1251 Third period from October 12, 1900, until September 30, 1901;

Fourth period, October 1st came the large investigation and continued until December 1, 1901.

The resumption of the collection and analyses of samples along the water route from Chicago to St. Louis in October and

November, 1901, was undertaken for the chief purpose of ascertaining whether the continued operation of the Chicago Drainage canal during the interval between the cessation of the investigation in October, 1900, and the resumption of the investigation for samples outside of St. Louis, in October, 1900, had produced any improvement of the sanitary conditions of the water as established by the former investigation along this route in 1900. I will now present a number of charts briefly explaining these conditions as we found them.

1255 This is chart number 11 for the investigation of 1901, October and November. This chart represents a comparison of results obtained from the analyses of water in the months of October and November, 1901, from the Illinois and Michigan Canal at Lockport; Des Plaines river at Brandon's bridge, Joliet; Drainage canal, Bear Trap dam, Lockport, and from the Des Plaines river above Bear Trap dam at Lockport.

The red line represents I. & M. canal; blue line the Des Plaines river at Brandon's bridge, Joliet; green line the Drainage canal, Bear Trap dam, Lockport, and yellow line the Des Plaines river above the Drainage canal—that is before they meet.

It will be seen from this chart that during that period the I. & M. canal was highly charged with free ammonia. It reached the figure of 22.4 parts per million of nitrogen in the form of free ammonia. During the last week a considerable fluctuation can be noted and at the time the collection and analyses was started the amount represented the figure of 18.8 parts
1256 per million of nitrogen as free ammonia. The same is true as to the chlorines found in the Illinois & Michigan canal at that time. We see variations there in the chlorine representing parts per million from 106 up to 150.8; then going down again within one week to 120.6, etc.

If we look at the nitrites we find fluctuations in the nitrites but notice that the nitrites do not fluctuate as much as the free ammonia and the chlorines. They are either absent or run up to a maximum of .15. Now that would indicate that the Illinois

& Michigan canal at that time was in a great state of fermentation. The action of the facultative anaerobic bacteria in this canal resulted in a considerable advance in the initial process of purification usually performed by these bacteria.

The variations in chlorine show that the amount of sewage coming into the Illinois & Michigan canal during this time, together with the varying amounts of free ammonia and nitrites, that the amount of sewage pumped into that canal must have been of great variable quantity. The water condition at that time may have been influenced by the action of the anaerobic bacteria somewhat and as it is an established fact that during the colder season of the year the purification process in the rivers is retarded considerably, the results would in a measure explain themselves. We see considerably less free ammonia in the main Drainage canal than we find in the Illinois and Michigan canal. The very high nitrites in the Des Plaines river after the two canal mix with the Des Plaines river at Joliet, show that the process of purification was in an intermediate stage as yet.

1259 Chart number 12 represents or gives a comparison of analytical results obtained from the daily collection of samples of water taken from the Des Plaines river above Bear Trap dam, Des Plaines river at the 9th street bridge, Lockport, and at Brandon's bridge, Joliet. It shows the result of the mixture of the water from the Drainage canal and the Des Plaines river and the result of the mixture of the Des Plaines river, the Drainage canal and the Joliet sewage in the Illinois & Michigan canal. Green line represents Brandon's
1260 bridge, at Joliet; red line Des Plaines river at 9th street bridge, Lockport, the dark line represents the Des Plaines river above Bear Trap dam.

1261 Chart number 13. The curves represent the comparison of the chemical character of the two canals at Bridgeport and at Lockport. Bridgeport is in Chicago on the south fork of the south branch of the Chicago river. Lockport is 29 miles from Bridgeport.

1262 The green color, or this top represents the I. & M. canal at Lockport. The red color or red line represents the I. & M. canal at Bridgeport. What I wanted to show by these curves is the remarkable fluctuations in the amount of free ammonia in that canal, showing its fermentative character. That is in the I. & M. canal as compared with the Drainage canal, the yellow line representing the Drainage canal at Bridgeport and the dark line representing the Drainage canal at Lockport. The ammonias in the Illinois and Michigan canal are very much higher, showing that the anaerobic bacteria have performed their work in the old I. & M. canal much more effectively than in the Drainage canal. The sewage in the Drainage canal as it reaches Lockport does not show very much improvement during its route from Bridgeport to Lockport. It demonstrates that the facultative anaerobic bacteria do not work so effectively in the main Drainage canal as they do in the I. & M. canal. The sewage from the Drainage canal is in a much more retarded state of purification. It is in a much cruder state and it is very much less purified in its initial state of purification at Lockport than the I. & M. canal sewage when it reaches Lockport.

Chart number 14 represents comparison of results of analyses of samples of water collected during the months of October and November, 1901, at Joliet and Peoria, Ill.

1263 The green line represents Des Plaines river at Joliet; the yellow line represents Illinois river at La Salle. The dark line represents the Illinios river three miles above Peoria. The very high results of free ammonia found in the water at Joliet are reduced somewhat by the time the water reaches Peoria. In other words, the initial process of purification has been materially facilitated during the transit of the water in the Illinois river from Joliet to La Salle and Peoria. This map will also show that the nitrites found in the Des Plaines river at Joliet at that time during those two months, were lower than the nitrites found at Peoria and at La Salle. While this would indicate that the process of purification had advanced somewhat for the sewage running down the Illinois river between those points, the very high nitrites found at La Salle and Peoria—at La Salle representing a maximum of .164 parts per millions and at Peoria a maximum of .154, I say they demonstrate that the process of purification of that sewage in the river coming from the main Drainage canal principally, and from the Illinois and Michigan canal, and from Joliet, that the process of purification has by no means been completed when the water reaches Peoria. The Illinois river, in other words, is found to be highly sewage polluted by the time it reaches Peoria. It is 124 miles between Joliet and Peoria. I wanted to say while the ammonias are much lower at those points of LaSalle and Peoria, they are still quite high and going with comparatively high chlorines and going with very high nitrites, that stamp the water of the Illinois river as it reaches Peoria as badly polluted water, during the entire investigation.

1264 Chart number 15 represents a comparison of results of the chemical analyses of samples collected during this period from October 1, to November 30, 1901, from Illinois river at the points of Beardstown, Peoria, Kingston, Pekin and Grafton. If we take free ammonias here we will notice that with the approach of colder weather the process of purification is retarded in the Illinois river as well as every other river in such climates. This demonstrates that if a wave of polluted water proceeds down the Illinois river, it increases the pollution of the Illinois river correspondingly during its entire course.

1266 Chart number 16 represents a comparison of the results obtained from the analyses of samples taken during the months of October and November, daily from a point in the Mississippi river several miles above the mouth of the Illinois and from the Illinois river several miles from its mouth. The blue line represents Illinois river at Grafton; the red line represents the Mississippi river at Grafton.

You will see that the free ammonias and the chlorines and the nitrites during these two months are always higher in the Illinois river than they are in the Mississippi river at Alton. Until the week beginning the 15th of November there was not much difference between the free ammonias of the two rivers although the free ammonias in the Illinois were always higher, but when the cold weather set in during the latter part of November, the free ammonia in the Illinois river went steadily up, so that finally on the 18th of December it showed one part per million of nitrogen in the form of free ammonia.

1267 Now, there is no corresponding rise to that extent shown in the Mississippi river, while there is an increase there in free ammonias and you can see the effect of the colder weather, yet the Mississippi river must not have been sewage laden to any extent whereas the Illinois river being a river of great instability because as we see, from the nitrites, the intermediate state of purification as represented by the nitrites, is varying continuously. In other words, if the Illinois river were not a heavily sewage laden river, the sewage would have been oxidized much more readily and better, but being in large quantities the effect of the colder weather proportionately retarded the process of purification so much the more and there being evidently considerably less pollution in the Mississippi river the effect of the cold weather there was not so material because of the absence of pollution to any material extent.

1270 Chart number 17 represents the results of the chemical analyses of the samples of water taken daily during the months of October and November, 1901, from a point several miles above the mouth of the Illinois river, represented by red line; the blue line representing a point in the Mississippi river one mile above Alton, the yellow line representing a point in the Mississippi river above Hartford, Illinois, and the green line representing the Mississippi river at Grafton, several miles above the mouth of the Illinois.

The free ammonia for the larger part of this period was lowest in the Mississippi river above the mouth of the Illinois.

It was the highest in the Illinois river several miles
1271 above the mouth of the Illinois and that for most of the
time the free ammonia at Alton and Hartford were higher than in the Mississippi river above Grafton, showing that the mixture must have taken place of the Mississippi and Illinois river after their junction resulting in an increase in the free ammonias at Alton and Hartford. That is for the larger part of the period. During one week the free ammonias were a little lower at Alton than they were in the Mississippi river above Grafton. They were also a little lower during the first week in October but only to a very small extent. For the remaining six weeks the free ammonia was higher at Alton than it was in the Mississippi river at Grafton. The highest free ammonia found during this period in the Illinois river was .17; the lowest .06. The highest found in the Mississippi river at Alton was .08 and the lowest is .04. The figures obtained for Hartford were almost like those found at Alton. The variation was slight. The maximum variation amounting to .015 so that I need not quote those figures. I will say the maximum variation showing that the free ammonias at Alton and at Hartford did not vary to any extent.

The chlorines we find lowest for this period in the Mississippi river at Grafton and we find it highest in the Illinois river at Grafton running as high as 26 parts per million. At all times during this period the figures for chlorine at Alton and Hartford were higher than those of the Mississippi river at Grafton and lower than the Illinois river at Grafton, demonstrating that the mixture of the two rivers had taken place in the channel from which the Alton and Hartford samples were collected, and demonstrating further with the increase in free ammonias and chlorines and also a corresponding increase in nitrites, an increased pollution of the Mississippi river from the higher polluted water of the Illinois river.

The nitrites in the Mississippi river above the mouth of the Illinois for this period were very low, as I have already stated for several weeks practically absent. The nitrites in the Illinois river during this period were comparatively high. The nitrites obtained from the Illinois of the samples at Alton and Hartford during this period, always showed an intermediate figure between the always lower figure from the Mississippi river and always higher figure from the Illinois river, clearly demonstrating the mixture of those two rivers and as a result, an increased pollution of the Mississippi river coming from the Illinois river.

1272 Chart number 18 represents results of chemical analyses of samples of water collected in October and November, daily in 1901 from Mississippi river at Hartford and at intake of St. Louis waterworks, Chain of Rocks, and from Missouri river at Fort Bellefontaine. The blue line represents the Mississippi river at Hartford; the green line the intake and the red line the Missouri river. The highest chlorines were found in the Missouri river. The lowest in the Mississippi river at Hartford and the chlorines at the intake represented during the entire period, an intermediate figure. This demonstrates that during this period a mixture of the waters of the Mississippi and Missouri was taking place in the Mississippi river after the junction of the two and its effect could be shown in the lower chlorines at the intake.

Hartford is one mile above the mouth of the Missouri river.

1273 It shows that the free ammonias during the months of October and November at these three points were not differing much. If at this time the nitrites of the Missouri river would be as high as those found in the Mississippi river at Hartford, or higher as was shown by the free ammonia, we could ascribe the higher free ammonia in the Missouri river to sewage pollution, but the nitrites are lower and since the high chlorines in the Missouri river are not attributable to sewage pollution of the towns and cities on the upper Missouri but are proven to be due to the drainage of the Kaw river through districts of Kansas containing vast areas of salt beds, it is to be concluded that the sanitary character of the Missouri river was better during this period than that of the Mississippi after it was joined by the Illinois river and increasingly polluted by the Illinois river. The figures for the nitrites at the intake tower during this period are almost similar to those of the Missouri river.

1274 Chart number 19 shows the correspondence between the curves representing the chemical examination of the samples of water collected during the months of October and November, daily, in the year 1901, from the Mississippi river at the intake tower at the St. Louis waterworks from the outlet of the St. Louis waterworks for the water as it passes through the reservoir. Now I want to demonstrate by this chart that there is a partial purification taking place in the reservoir. The average amount of sediment that remains in the reservoir is 85 per cent. Now, while the sediment remains in the reservoir to such a large extent the quantities of impurities are not reduced so much—they are reduced some, but it is very small. So small that practically we can say that the amounts of free ammonias and chlorines found in the water at the intakes and the amounts found in the outlet of the reservoir do not differ materially. As regards the nitrites, there is some oxidation taking place in the reservoir at times, but we will see that the nitrites for the month of October do not vary much in the reservoir.

This shows that whenever the impurities rise in quantities in the water from the Mississippi river at the intake, a rise in quantity of these impurities follows in the reservoir and follows in the water taken from the tap of the city water supply. What I said for free ammonia applies also to nitrites as you can see from these curves and it applies to the chlorines and in a measure to the nitrates.

1276 In November and December, 1901, samples were collected from points in the Missouri river about the mouth of the Missouri, at following places. (Witness in each instance gives result of analyses.)

Missouri river, above Omaha, near Nebraska shore.

1277 Ten miles below Omaha at Belle View, Neb.

1278 These results show that the Missouri river, as it approached Omaha, Neb., on November 13 and November 24, was polluted as shown by the presence of free ammonia, nitrites and chlorine. However, the nitrites found on both days being very low, showing only .004 parts per million on November 13 and .001 parts per million on November 24, together with comparatively low free ammonia and chlorine, and demonstrating that the pollution cannot be designated as sewage pollution.

1279 Sample was collected from pump house of city of St. Joseph on the Missouri river on November 14, 1901.

Sample collected 12 miles below St. Joseph.

November 26, sample collected from Missouri river at St. Joseph near waterworks and November 25 at Wathena, Kansas, 12 miles below St. Joseph.

1281 Sample collected on Missouri river, November 17, ten miles below Kansas City.

From Kaw river at Argentine, Kansas.

November 28, sample collected from Missouri river at Kansas City at the point where the waterworks of Kansas City are located.

1282 Ten miles below Kansas City.

Kaw river, at Argentine, Kansas, November 29.

One mile above Jefferson City, November 19, 1901.

1283 November 19, five miles below Jefferson City.

December 1, 1901, above Jefferson City.

December 1, 1901, five miles below Jefferson City.

1284 November 20, 1901, Missouri river one mile above Hermann. Hermann is between Jefferson City and St.

Louis, 125 miles from the mouth of the Missouri.

November 20, three miles below Hermann.

1285 December 1, one mile above Hermann, Mo.

December 1, 1901, three miles below Hermann, Mo.

November 22, half a mile above St. Charles.

November 22, one and one-half miles below St. Charles.

1286 December 3, one-half mile above St. Charles.

December 3, one and one-half miles below St. Charles.

1287 These examinations show with reference to chlorine in the Missouri river that there is an accession of chlorines in the Missouri river at Kansas City from the Kaw, also called the Kansas river, a river which has a length of about 300 miles and drains through a number of counties in which large salt deposits have been located, as it is reported by the U. S. Geological Survey.

The chemical analyses show that the Missouri river as analyzed from Omaha down to St. Louis, has a character of considerable stability. The results are pretty much uniform along the route, with the exception that the high chlorines coming from the Kaw river increase somewhat the amount of chlorine in the Missouri river between Kansas City and St.
1289 Louis. The data on these sheets represents the analytical results obtained from a chemical examination of samples of water collected from various points indicated upon the table which samples were collected and the analyses of the same performed daily during the months of October and November, 1901.

Q. That is enough. The table can be inserted here.

(Table not subsequently furnished F. S. B., Com'r.)

The fifth period of investigation began on December 1, 1901, and continued to July 1, 1902. As already stated yesterday, during this period samples of water were collected above Chain of Rocks from two points only during this period, that is from the Illinois river several miles above the mouth of the Illinois river at Grafton. Daily samples were collected until

December 18, 1901, and daily samples were collected from the Mississippi river a few miles above the mouth of the Illinois river from December 1, to December 14, 1901. With the exception of these samples taken at Grafton from the two
1290 rivers, there were no samples collected from any point during this investigation above the Chain of Rocks, St. Louis, in the Mississippi river.

Five samples were collected daily during this investigation. Three from the Mississippi river at Chain of Rocks opposite St. Louis waterworks—one from Illinois shore, one from entrance to intake tower, one from the Missouri shore, one from outlet chamber of waterworks and fifth sample from tap in city chemist's office, St. Louis.

I have shown in the curves on chart number 16 presented yesterday, the results of the analyses of the samples of water taken from the Illinois and Mississippi river at Grafton from December 1, until December 18.

1293 The investigation, as far as reported to the authorities, terminated on July 1, in the laboratory of the city chemist's office because of the removal of that office to new quarters in the old city hall. After the equipment of the new laboratory in the new city hall, the investigation was resumed on October 1st and continued until January 1, 1903, as follows:

Three samples were collected form Mississippi river at Chain of Rocks, one close to Illinois shore, the other close to Missouri shore and the third one at the intake. Daily samples were also taken during this period from the outlet chamber of the waterworks and from the tap in the new quarters of the city chemist's office.

The results of these analyses do not show any improvement in the sanitary quality of the water supply of St. Louis as compared with the results obtained from the various investigations conducted in the city chemist's office since August 23, 1899.

I consider the Lake Michigan water as it enters the Chicago river, polluted. It is not a pure water. From my examination of the streams, it is my opinion that the waters of the Drainage canal pollute the Des Plaines river.

1294 The Illinois river is polluted by the Drainage canal indirectly through the Des Plaines river. I can state from my examination of these waters that the water coming into the intake of the St. Louis waterworks is now less wholesome or less pure and less fit for sanitary use and domestic use than it was before the opening of the Drainage canal..

In analyzing water the most accurate results analytically are obtained from samples collected daily.

The English River Pollution Commission was created in 1866 by the British Government for the purpose of investigating the question of the pollution by sewage from cities of the rivers in Great Britain. The investigations cover a period of eight years. During this period six reports were published. It was perhaps the most comprehensive investigation of the kind ever attempted until then and while a variety of opinions have been expressed as to the conclusions to be drawn from these reports, the predominating opinion after the publication

1295 of the reports—

ATTORNEY GENERAL HAMLIN: I object to any opinion given by the English Commission or any statement as to what those reports contain on the ground, first, that the reports would be the best evidence; second, that the evidence is not relative to the issues here.

MR. TODD: The Sanitary District joins in the same objection with the State.

A. The predominating opinion among sanitarians has been that the pollution of streams by sewage from cities and towns located on the banks of these rivers should be prevented by legislation, because the investigations conducted by the commission resulted in establishing the fact that pollution of streams by sewage of towns and cities in England was being carried on to an extent rendering the streams unfit for drinking purposes.

ATTORNEY GENERAL HAMLIN: I move to exclude all of the answer to the last question for the same reasons that are given in the previous objection.

MR. TODD: The Sanitary District joins in the same motion.

In Kansas City, the development of the sewer system did not keep pace with the growth of the population and as a result today only 60 per cent of the sewage of Kansas City goes into the Missouri river. There are as many as 4,000 cess pools in Kansas City into which the sewage of the city is placed and kept there for some time, until the tanks are filled up and the sewage is then disposed of in various ways, used for manuring purposes—some burn it up, and about one-fifteenth of this sewage eventually reaches indirectly the Missouri river, but when it reaches the Missouri river it is sewage far advanced in its purification or rather in its oxidation and has an en-
1296 tirely different character than the fresh sewage run into
the river from the sewers. The water of the Missouri river is better for use for domestic purposes and is a more sanitary drinking water than that of the Mississippi river at the confluence of the two streams. The Mississippi river above the mouth of the Illinois river is better for drinking purposes than the Mississippi river above the mouth of the Illinois.

The water coming into the intake tower in January, 1900, and from that time on, as a rule has not been potable. I am familiar with the theories of Tidy and Letherby and other English scientists with reference to the effect of sewage upon running streams. The theory of Tidy and Letherby originally attracted much attention. It practically amounts to this, that sewage diluted in pure water at the ratio of one part of sewage to fifteen parts of water would purify itself after running a distance of about 10 or 12 miles. It was this very theory
1297 that in its application in England proved to be falla-
cious in many instances, that led to the creation of the

Rivers Pollution Commission in England to which you referred in a previous question. The result of this investigation was that a new theory practically supplanted the theory of Tidy and Letherby in England, and that is that there is no river in England long enough to purify itself. I consider Tidy and Letherby's theory from the facts ascertained by a careful study of the question of river pollution, as antiquated and overthrown by the experiences of many communities in England as well as in other counties. This theory of Tidy and Letherby was tested, so to speak, by investigations carried on in England on the rivers Irwell and Mersey, by Frankland, a prominent chemist and sanitarian of England in the seventies. The conclusions drawn by Frankland from these investigations were that sewage discharged into a river at the ratio of a dilution of 1 to 15, instead of purifying itself after a run of from 10 to 12 miles, only two-thirds of the sewage would purify itself after running a distance of 168 miles.

The Illinois river, after the opening of the Drainage canal, showed its highest stage at Grafton on January 21st, when it showed 5.9 feet. It then began to fall steadily until February 3, when it showed only one foot at Grafton. Then there began a rise steadily from day to day and within a week the stage was 7.3 feet.

1298 It remained close to that figure for the following week.

In the third week in February the river took a sudden rise on the 21st. On the 20th the stage was 6.9 and the following day it was 8.3 and it remained at 8 feet and went up to 8.5 and in the following week began to fall again down to 7.4, 6.1 and at the end of the week was 5 feet.

It rose from the 5th to the 6th of March from 5.1 to 7 feet. From day to day it rose averaging a foot until March 13 it reached 14.8 feet. March 14, 16.1; March 16, 17.3. That was the highest in March and then it fell steadily. For the next month it remained pretty steady around 12 feet.

1299 The Mississippi river at Louisiana, Mo., showed during the month of January, 1900, throughout, a very low stage varying between 1 and 3. There was a period of very cold weather prevailing at that time and in the beginning of the month in the first week the river was frozen over and again at the end of the month, so that would have to be taken into account in calculating the measurements. Hence, there are such low figures as .7 which means seven tenths of a foot. The stage of three feet was only reached once during that month, on January 19th, for the major part of the month the height of the river varied between one and two and one-half feet. These estimates are based upon the regular gauge of the river as taken for the U. S. Weather Bureau.

1300 In February it was about the same the first week. In the next week it went up to 3.8 and in the following week it showed some slight variation only from 3.4 to 4 feet the highest reached during the month and at the end of the month it fell to 1.5 feet. It remained low again for about a week in March when it rose again to 12 feet on the 15th of March after which it fell steadily until the last week of March when it was 5.1 feet.

1301 The fall in the rivers, the Illinois and Mississippi at those points continued until the 3d day of April when there was a corresponding rise again in both rivers to 8.7 in the Mississippi river and 13.6 in the Illinois river at Grafton, which was the maximum gauge for both rivers during that time. They began to fall down to 5.9 for the Mississippi and 11 feet in the Illinois river during the next week and during the last week of April both rivers rose about one foot reaching a maximum height during that week of 8.4 feet for the Mississippi river and 12.7 for the Illinois river. In other words during this month the heights, the rises and falls in the two rivers were corresponding for the month of April.

Am not acquainted with the waters of the Drainage canal or the Chicago river and its different branches prior to the opening of the Drainage canal in 1900. I had seen these waters

when I was in Chicago. Prior to the opening of the canal, most
of the times when I was in Chicago the Chicago river
1302 had the appearance of a dark colored sewer water
emitting offensive odors and gas bubbles. The water in
the I. & M. canal had the appearance of sewage and it was also
of a dark color and emitting offensive odors and gas bubbles.

The Pettenkofer theory of the effect of pollution of waters upon running streams was that sewage discharged into a river and diluted at the rate of one part of sewage to fifteen parts of water would purify itself after a run of fifteen miles, provided that the velocity of the river into which the sewage was being discharged, was at least about the velocity of the sewage and that this velocity was at all times three-fifths of one metre which is equal to about two feet and one inch per second; that would
be the least velocity per second.

1303 That theory was advanced first sometime in the seventies.
That theory does not maintain today among sanitary scientists in water supplies. One of the greatest difficulties in the country is that running streams in themselves are not pure. The ratio of dilution is based upon a mixture with pure water and whenever the ratio is applied, of a mixture of sewage with polluted waters, it proves to be fallacious. It is true that a number of scientists have declared in various instances and quoted in scientific publications that the theory proved to be successful, but other investigators have shown that those investigations upon which these scientists based their conclusions were carried on in an inaccurate manner. For instance, it was proven that the velocity of the current differs—that is the velocity of the water running along the shore and the velocity of the water running in the channel differ. The velocity on the surface differs from that in the middle depth of the river. The velocity of a channel is greatest in the middle of the depth of the river. Now, in taking samples a great many of these investigators who agree with Pettenkofer evidently have made the mistake of taking samples from

the surface. The character of the water on the surface is different than the character of the water at the middle of
1304 the depth—that is, oxidation processes are somewhat facilitated by light, and the top water in the channel would present a different chemical character accordingly than the water running at a certain depth, as I said before. Therefore Classen, who is a chemist of much distinction in Germany, and water specialist, and others, challenged the correctness and reliability of the analytical results upon which many of the followers of the Pettenkofer theory base their conclusions that Pettenkofer theory was correct. They proved contradictory data showing that this so-called self purification was in reality impossible, etc. These investigations have been published in one of the greatest works that has been written on the pollution of waters, by an investigator of great eminence in Germany.

That is Julius Koenig and the title of the work is "Die
1305 Verunreinigung Der Gewasser," published in 1899.

According to the researches as described in this work a conclusion is justified that the oxidation of sewage discharged in the rivers depends so much upon various conditions and circumstances constantly varying and differing so materially as applied to various streams, that a hard and fast rule as to ratio of dilution cannot be considered reliable any more.

I have a table showing the average daily and weekly rate of flow in cubic feet per minute of the water in the Drainage canal, the I. & M. canal, the Chicago river at Chicago, the Des Plaines river at Riverside, the Des Plaines river at Joliet for the years 1900 and 1901, secured from Mr. Todd, and compiled by L. E. Cooley, assistant engineer of the Sanitary district. In September, 1900, the Drainage canal was closed during the day time for several weeks excepting Sundays. The volume of water running over the dam at night is estimated and represented in the table there. There was some water coming in but in comparison to the regular flow it was a small flow.
1306 The daily closing of the Drainage canal at that time in September, 1900, resulted in the reversion of the flow

of the Chicago river back into the lake and as I have already testified evidently resulted in an increase of the pollution of the water taken from the lake front, and as I also testified, I believe that the Chicago river at that time in the reversion of the flow back to the lake again assumed this character which it had shown prior to the opening of the Drainage canal, that is its color was darkened again and offensive odors and gas bubbles were noticeable along the route of the Chicago river during that period. After the re-opening of the canal with the average regular flow, after that time of temporary closing in September, 1900, the accumulated accretions of Chicago sewage in the Drainage canal being discharged into the Des Plaines river and subsequently into the Illinois river, resulted in increased pollution of these rivers as traced along the route down to the mouth of the Illinois by the analyses of samples collected at points between Chicago and St. Louis at that time.

1307 After having made these examinations I can say that the sewage in the outfalls of the sewers in Chicago goes into the Drainage canal, the Illinois river and into the intake of the St. Louis waterworks.

From these examinations I am able to state that the water of St. Louis is more polluted now by reason of the opening of the Chicago canal and the inflow of the sewage from Chicago than it was prior thereto.

THOMAS A. BUCKLAND, examined by Attorney General Crow:

Am Assistant City Chemist of St. Louis. Have occupied that position for about ten years.

1308 Took part in the examination of the waters under consideration. Worked in the office or laboratory of the city chemist in the city hall. States methods used, etc.

1313 HENRY DETTMER, examined by Attorney General Crow: Am a chemist. Was educated in Germany. In

1314 1900 I was engaged by Dr. Teichmann in this case especially for the purpose of determining the total solids, and at the present time I am first assistant chemist in our milk examination department in the city chemist's office.

States methods pursued in doing the chemical work and analyzing the samples of water heretofore testified to.

1325 SHERMAN LEAVITT, examined by Attorney General Crow: Am a chemist. States previous experience. Was connected with Dr. Keiser as his assistant for about a year and I worked on this work in the city chemist's office under Dr. Dettmer. I worked on the total solids for Dr. Dettmer.
1326 I was under him. States methods employed and course pursued, etc.

1331 CROSS EXAMINATION by Mr. Johns: Generally the analysis was made the same day samples arrived. We couldn't keep up if extra samples were sent in as they were very often. We would get three or four days behind.

1343 WILLIAM H. GOETZ, examined by Attorney General Crow:

1344 Am civil engineer. Have studied chemistry. I had two years at college and then my experience since. Worked on samples collected for Dr. Teichmann. I performed
1345 the analytical work, and working up the results afterwards, getting them tabulated and averaged in the form of charts. Did all my work in the city chemist's office. States methods pursued.

1364 ALEXANDER N. MILLER, examined by Attorney General Crow: Am a graduate civil engineer, that is I am a graduate in civil engineering. Studied chemistry in connection with my course in civil engineering at the University of Cincinnati from which I graduated in 1897. Have been employed on this investigation by Dr. Teichmann, as analy-
1365 tical chemist. States methods used in the laboratory and also method employed in making sheets showing results of analyses. (Former witnesses also testify to latter fact.)

1372 JOSEPH F. SONDAG, examined by Attorney General
1373 Crow: Am a druggist by trade but since October 1,

1901, I have been employed in the city chemist's office as a clerk. I was assistant at the distillation table and took part in the analyses of the waters brought in from the Mississippi river. I worked under the direction of Dr. Teichmann.

States methods pursued, etc.

1377 THOMAS A. BUCKLAND, resumed the stand and was examined by Attorney General Crow.

States what part he took in the analytical work.

1378 I know from my own recollection that I found the ammonias quite high in December, 1901, in the Illinois river at Grafton. The maximum amount I found was somewhere in the neighborhood of one part per million. According to my recollection the ammonias run rather high for the samples taken at the intake during the subsequent months.

CROSS EXAMINATION by Mr. Johns.

1379 I am not prepared to state what caused the ammonia to run high in the Illinois river at that time. I presume it was from pollution in the Illinois river farther up. According to my recollection the state of the ammonias in the Mississippi at that time, was lower—the free ammonia was lower. I do not remember the state of the Mississippi as to ammonia on that same day. Nor of the Missouri. I am not able to state whether the Mississippi was at that time as to ammonia, higher or lower than a fair average. Nor the Missouri.

1380 DR. WILLIAM C. TEICHMANN, resumed the stand for cross examination by Mr. Johns.

Q. What is your idea or reason for calculating the volume of the Illinois river and its flow per minute or cubic feet, or per second of cubic feet, to place it at the extremest low water that you could find data for?

A. The low water stages are the most important in my opinion in calculating the effect of the sewage on the Illinois river, because of the lower volume of water producing a lower ratio of dilution. The idea was to calculate the smallest

1381 amount possible of dilution for the purposes of calculation of the dilution of the river.

A low water stage might continue for a day or a week or ten minutes.

Q. And the very lowest stage is extremely rare and a very unusual thing, is it not?

A. Well, that depends upon the weather conditions very much. But the very lowest stage of the river is the thing which occurs less frequently than an average or a mean stage of the river. I got my figures for the low stage of the Illinois from a report published by Lyman E. Cooley, formerly chief engineer of the Chicago Drainage canal made in the year 1890. I have data as to the stage of the Illinois river from 1890 to 1899. I got those records from reports published by the Illinois State Board of Health up to 1899, in which the stage of the Illinois river was given at various times by Civil Engineer Harman. I did not take some time nearer to the opening of the canal than 1890 as the basis of my data because I thought
1382 that the lowest stage on record would be exactly the stage to take because it might possibly recur again, this lowest stage, and the lower the stage of the river of course the smaller will be the amount of water for dilution of the sewage in the river, and worse than the amounts of pollution shown on the charts.

In your testimony of March 17th, you have the lowest stage at Wilmington, on the Kankakee, 25,200 feet per minute, on the Des Plaines 256 feet and at another time you have for the Des Plaines 339 cubic feet—in the Fox river, 31,339 feet per minute; the Mason river 15,000 cubic feet and the canal at La Salle 37,900—that would make 110,034 cubic feet or 18,339 cubic feet per second. The rivers named are above Utica.

Q. Then where do you get your basis of 600 cubic feet of water, upon which you calculate the basis of dilution and pollution?

1383 Well, Mr. Johns, the question is whether my testimony on that day conveyed that idea. Of course I am not sure about that just now, but certainly the figures that I presented there would lead to the conclusion that the flow was considerably less than 18,339.

Q. Well, now, how do you happen to assume the sewage of Chicago at 400 cubic feet per second?

A. Well, figuring on the amount of sewage coming from the I. & M. canal, it is simply that the flow per minute is converted into seconds; they would have to take sixty times that; that would give you a certain figure per minute, and that would be the flow from that sewage.

Q. If you have any data or know any way in which you can figure that the sewage of Chicago is 400 cubic feet per second, state now what it is and how you arrive at that conclusion.

A. Well, that was at that time from the Illinois & Michigan canal based on the theory that there is 60 times—figuring on 36,000 per minute of flow.

Q. Assuming that the discharge from the Illinois and Michigan canal was 36,000 per minute, and that 60 per cent of that flow was Lake Michigan water, 40 per cent of it then you say would be sewage?

A. Yes, from Chicago. 40 per cent of 36,000 would be two-fifths—40 per cent would be 14,400. That would be 240 feet per second.

1384 Q. Then where did you get your figures of 400?

A. Well, you must take the total volume of the sewage mixed with the water as it leaves the canal.

Q. That is precisely what I am doing, and assuming that 60 per cent of the flow of 36,000 feet is Lake Michigan water, dilution, and 40 per cent is sewage as you say, then your statement of 400 feet per second for Chicago sewage is incorrect, is it not?

A. No, I don't think so because the sewage as it leaves the canal is supposed to be the sewage mixed with the lake water there. It is diluted sewage; you can't base the calculation on the sewage there, because it is mixed with the water and leaves the canal together; that is what is understood by the sewage leaving the I. & M. canal. It is of course the sewage mixed with the water there.

Q. Well, you say at the ratio of 40 per cent sewage to 60 per cent Lake Michigan water, so that your assumption of 400 feet was incorrect by 140 feet, was it not?

A. No, sir, not the way I construe it, and the way Mr. Cooley and Mr. Harman construe it in their reports. They calculated on the total volume leaving the canal and entering the Des Plaines river, or rather at La Salle and call it all sewage.

Q. If the flow from the Illinois and Michigan canal is 36,000 feet per minute, and if 40 per cent of that is Chicago sewage; then assuming that state of facts, without any argument with reference to it, your assumption of 400 cubic feet per minute of Chicago sewage is a mistake, it is not?

A. No, I can't admit that, because the mixture there is still sewage.

1385 Assuming that the volume per second of the Illinois river above Utica is over 18,000 feet and that the sewage of Chicago is 400 feet per second, your rate of dilution of 1 to 5 is also incorrect, is it not?

A. Well, based upon your premise.

Q. Assuming that the volume of the Illinois river above Utica before the opening of the Drainage canal was in round numbers 18,000 feet, and that the sewage of Chicago was 400 cubic feet per second, what is the ratio of dilution?

A. One to forty-five. That is a very considerable dilution.

Q. Do you know that in this calculation that you have made here of the stage of the Illinois river above Utica, you have left out a number of rivers?

A. Well, those rivers were left out because in the opinion of Mr. Cooley, their stages were such that they were practically
dry during that season of drouth, so that Cooley omitted
1386 them from his calculations. My entire argument upon
the question of the dilution of sewage is based upon an

opinion of Mr. Cooley, given in 1890 and also upon an opinion in figuring out those stages and averages, presented by Mr. Harman, published in 1901.

Sewage is the discharge of matter from cities through tubes into some place of exit, including various kinds of discharges. The discharge of sewage in Chicago in 1899, in December would have to be calculated with the water supply. I
would make it for Chicago, 42,000,000 cubic feet per day.
1387 I figure that the amount of sewage amounts to the water
supply of the city without any kind of deduction. That
is an approximation, of course. The figure may not be absolutely correct, but it is an approximation that is accepted by all engineers and practically all text-books on engineering. That's a scientific argument, though that is the basis upon which investigators carry on their investigations, engineers.

Q. By whom, for instance?

A. Well, now, I cannot quote any particular one just now,
but it is usually recorded in various text books.
1388 If the water is converted into steam it doesn't return into the sewers, or if it is consumed by animal or man, or if
is destroyed in the purposes of some manufactory and its identity lost, it does not again return to the sewer as water.
1389 Assuming that it is 42,000,000 cubic feet per day, that
would be 291,666 cubic feet per minute.

Q. Now where did you get your estimation of 400 cubic feet per minute, for the sewage of Chicago.

A. That is the I. & M. canal at that time. The total amount of the sewage of Chicago was not pumped into the canal at that time. Only a part of it. I calculated on 36,000 cubic feet per minute. That was the water pumped at the Bridgeport pumping works.

Adding chlorine to absolutely pure water would be adding
impurity to it.
1390 Q. What amount of chlorine in water would make it
unpotable to a resident of Missouri?

A. Well, I claim that there may be as much as 500 parts chlorine in that water and yet it may be potable.

Q. If there is any standard, state it, for chlorine in potable water.

A. No standard would be recognized that would condemn water solely on its contents of chlorine. In itself, considered alone, as a constituent in the water, it is the same when you find it whether it comes from dissolving salt or from a dissolving manure heap, chemically, if you leave out of consideration everything else and simply look to the chlorine. It is identified the same way and it is present. Solely as such it is not an element of pollution in water without reference to its source. However, that depends upon what you define as pollution. If entering pure water, it may add impurity to the water, but is generally considered as pollution, I cannot class it with that.

1392 The general definition of pollution in water, is understood to be pollution principally by organic matter and I do not call salts and minerals organic matter, of course. When I find chlorine in water, I cannot tell, considered by itself and separate from all other things, whether it comes from organic matter or mineral matter. Albuminoid ammonia having a number of organic compounds is an element of pollution in water. It is an evidence that in that water there must have been some organic substance. These organic substances may be fecal discharges or the result of dissolution of plants or it may be both. If albuminoid ammonia was to be attributed to the decomposition of fecal matter, it would be the highest in the Mississippi river, in June, July and August. That would apply very well to all rivers and to all waters.

1393 It would be higher in the waters of the Illinois if attributable to vegetable substances, in September, October and November, as a result of the decomposition having taken place during the summer months, of vegetable matter.

Q. When you find albuminoid in water in the Illinois river at Grafton, can you tell whether it comes from decomposition of animal organic matter or vegetable organic matter?

A. In a measure I will be able to distinguish approximately
whether this albuminoid may be more of animal origin
or vegetable origin, by comparing the results for oxygen
1394 consumed, etc. We take all these things in general together
and that enables us in a measure to say approximately
and form an opinion as to whether the albuminoid ammonia
there may be of animal origin, principally, or of vegetable
origin. It is an approximation, but in general we can
draw some conclusions from these comparisons.

I found nitrites in the Illinois river at Grafton. I cannot tell whether they are from the decomposition of vegetable or animal organic matter, taken by themselves.

My theory is that the I. & M. canal was in a way a septic
tank, and that therefore the waters discharged from it into the
Illinois river at Joliet were in a better condition chemically
than the waters discharged into it by the drainage canal. I
never made any chemical analyses of the waters of the Illinois
river at Joliet before the opening of the Drainage canal; I did
not have anybody do that. So as to what was the condition of
the Illinois river at Joliet consequent upon the discharge of the
Chicago river through the I. & M. canal prior to the opening of
the Drainage canal I do not pretend to know from my own personal
analytical examination.
1395 So that I have no personal knowledge in any way of the
conditions chemically either above or below the place
where the Drainage canal flows into the DesPlaines river, prior
to the opening of the canal as I made no examination of it.
If a septic tank is good at one place it ought to be good at another
place in the course of decomposition. Water is only purified
to a certain extent in a septic tank—so it would not be benefited
by passing through a second septic tank.
1396 It has been established that in these septic tanks the
aerobic bacteria are present to a limited degree and these
aerobic bacteria by being present in subsequent tanks may to a
small degree continue these processes of purification and produce
a purified product, that is, as far as they are able to do so

in that tank. In the I. & M. canal there was some current of water. The current is exceedingly slow and it depends very much upon the amount of sewage pumped into the canal and how long it is permitted to be in the canal. It varies greatly. If 36,000 cubic feet per minute were pumped in and 36,000 cubic feet per minute discharged there was a current in the I. & M. canal at that time. If that was the average state and condition, it must have had somewhat of a current.

If below where the I. & M. canal discharged into the Illinois river there was a stretch of river of say three miles, in which the current was very slow, scarcely perceptible, that would operate as a septic tank.

1397 If there was another stretch of 23 miles that would also operate as a septic tank. In any investigation of the Illinois river that I have made, a long and continued series of septic tanks would have been very beneficial to the purification, in a measure. I know that upon the Illinois river there are a large number of bayous and lakes, adjoining the banks of the Illinois river, which are spring fed and which in low water discharge their water into the Illinois river and which in high water are completely overflowed. They could operate as septic tanks. From my own personal study I don't know whether they do or not.

In the course of the investigation we took cross sections of the Illinois river. We took some at Joliet and then at points below Peoria and Pekin. We took one at Kingston, Illinois, which is eight miles below Pekin.

1398 The cross sections taken at Pekin and Peoria represented three sections across the river—we took the center of the river and then the right and left shore. I have not as yet presented the result of the analyses of these cross-sections. The average stages of the Missouri, Mississippi and Illinois

1399 rivers from August, 1899 to January 22, 1900, were comparatively low. (Table No. 1.) This is the table of the data for 1899, compared with the Illinois and Mississippi rivers at Grafton.

1399 MR. JOHNS: We would like to have the table presented showing the results of the analyses of each sample at that place at this time. We don't understand that table has ever been given.

1400 I don't recollect just now how many samples we took from September 6, 1899 to January 17, 1900. There were 18 samples taken.

1402 I got the information that only 47 per cent of the population of Peoria discharged its sewage into the Illinois river from a report published by Mr. Harman, civil engineer, in the Illinois State Board of Health report of 1900.

1403 I don't know that by any personal examination. I know that at Peoria there are a number of large distilleries and very large glucose works and that there are a great many other manufactories in the city of Peoria. I know that in these distilleries a very large number of cattle are fed and that the sewage from this city of Peoria, in proportion to its population is enormously large. I won't admit that it is very much disproportioned to the amount of the water supply as discharged from its sewers into the river. I know that quite an amount of sewage and refuse matter is dumped into the Illinois river at Peoria, between Peoria and Pekin. I do not admit it is disproportionate to its population.

1404 Q. Did you ever see floating down the Illinois river islands of discharged animal matter, combined with straw, and find them sixteen and eighteen miles below Pekin, 25 or 30 miles below Peoria?

A. I haven't seen such, but I have heard of so-called floating islands coming down the river there and being recognized by parties in the towns below Peoria, between Peoria and Beardstown.

Q. Now, that is a very unusual state of affairs, isn't it?

A. I have seen some of these so called little islands myself. I remember now, in the trips I made down that river on such occasions.

1405 Q. If the sewage of Peoria will purify itself, if the dilution which it receives from the Illinois river, in a run of from 25 to 50 miles down the river, why will not the sewage of Chicago discharged at Lockport, purify itself in a run from Lockport to Peoria?

A. First of all, the sewage of Peoria cannot purify itself by such a run of from 25 to 30 miles under the conditions prevailing in the Illinois river. That is, the water of the Illinois river as it reaches Peoria not being sufficiently pure. The water in the Illinois river as it reaches Peoria and passes down is confined to the current in the Illinois river. There is water outside of the current, but it is the current of the Illinois river that carries the water of the Illinois river down that river. There is a different speed of the river in the channel from the speed along the shore.

1406 The sewage as it enters the Illinois river from the sewers does not reach the channel right away. It remains along the shore and since it has been established that the velocity of the river along the shore is always slower and different from the channel itself and there being quite a number of impediments there, the river makes certain curves between Peoria and Pekin, there is a considerable slackening of the speed of the river along the shore and this sewage from Peoria has a considerable time to perform certain initial purification processes along its route whereas in the channel the current is faster and this sewage from Peoria when it reaches the channel finally has remained for some time along the shore and has undergone certain processes of initial purification. The chemical analyses of cross-sections show that. In a measure we can call that a septic tank.

Q. Now, if the waters of the Illinois river were potable when the sewage of Peoria was deposited in them, and if the waters of the Illinois river were of the same volume as they are now with the drainage canal open, would the sewage of Peoria purify itself in 25 or 30 or 50 miles?

1407 A. If that water, the Illinois river water, as it reached Peoria, would be pure, from the analytical data obtained, from the examination of samples of water collected between Peoria and Grafton, the conditions as described by me prevailing in the Illinois river, between Peoria and Kingston, and through the lower towns there, these analytical data would demonstrate that chemically the effect of the pollution of the Illinois river by the Peoria sewage would not be noticeable. I previously said it would take from 25 to 50 miles for that sewage to disappear in the channel of the river, not to be noticeable in the channel of the river, the effect of it.

MR. JOHNS: You are to assume that the waters of the Illinois river at Peoria are potable, and of the same volume as when the Drainage canal waters flowed at that point, and at that point they receive the sewage of Peoria, would not those waters purify themselves so as to be again potable in a run of 25 or 50 miles, and I would like you to answer yes or no.

A. Whether that sewage would be purified or not, absolutely purified or not, that is a question I cannot answer, because, as I said, the water in the channel shows a different character from the water along the shore, and samples taken from the channel from 25 to 50 miles below Peoria do not show any more, chemically, the effect of the discharge of sewage of Peoria into the river. That don't preclude that the Peoria sewage may still be, partly, in a partly decomposed state along the shore, not in the channel, and may still necessitate further purification before it could have disappeared, from the anayltical results. 1408

(Question repeated.) A. As I have stated before, a chemical analysis of the water taken from the channel 25 to 50 miles below, would not show any more the presence of the sewage from the city of Peoria, but that would not preclude the sewage from the city of Peoria still being in the river along the shore, undergoing its natural processes of gradual purification.

1409 Assuming that the waters of the Illinois river when they reach Peoria, are potable, and of the same volume as when the Illinois Drainage canal is discharged into them, and that at that point they receive the sewage of Peoria, would these waters become potable again in a run of from 25 to 50 miles?

A. I don't think they would; that is, potable in general.

Q. Would they become potable in a run of 75 miles under the same circumstances supposed in the previous question?

A. That would depend very much upon the character of the sewage of the city of Peoria.

Q. You made a statement on March 17th, that the sewage entering the Illinois river from the city of Peoria, after running from 25 to 50 miles, would purify itself so as to remove the polluting effect of Peoria sewage on the Illinois river? (See rec. 1214.)

A. I said chemically, yes. I didn't say at that time, but it was understood, and if I had been asked the question I would have said so at that time, that a chemical examination of the samples of water taken at a point below Peoria, and taking into consideration the general conditions of the river, I would say
that that sewage disappears from the channel, that is,
1410 the chemical result would not show its presence in the
channel.

Q. 25 to 50 miles below Peoria, do you think it would show its presence along the sides of the channel?

A. The cross-sections that we have taken from the Illinois river below Peoria show chemically a difference between the water running along the shore and running in the channel.

Q. Does it show in the Illinois river on the sides, or would it show, and not in the channel, 25 to 50 miles below Peoria?

A. That I couldn't tell because I haven't made any examination of samples from that point. I have not produced any analyses of the cross-sections which show any such results here.

The samples of water which I took from the Illinois river were all taken within the channel. The orders issued to the collectors were that they should always take them from the channel. When I took samples at the Chain of Rocks, on the Missouri shore the sample was taken as close to the Missouri shore as was necessary to get a characteristic sample of the Missouri river water as it hugged the Missouri shore.

That part of the river which runs close to the Missouri shore is composed principally of Missouri river water.

Q. Run a line two miles up the current of the Missouri river and a line in the current of the Mississippi river at the junction of the two, and what would the angle be?

1412 A. That would produce an angle.

Q. Produce pretty close to a right angle, wouldn't it?

A. Yes, sir.

Q. Well, when there are equal stages of water, and in an average condition, your theory is that the current of the Mississippi overcomes the current of the Missouri and turns it down the Missouri shore towards St. Louis.

A. No, not exactly; it don't turn it over to the shore so that the Mississippi river would prevail. The two currents will run alongside of each other, each river hugging one shore —the Missouri hugging the Missouri shore, and the Mississippi river hugging the Illinois shore. Now, it will depend entirely upon the volume of water in each of those currents which will prevail in the channel—of the channel water.

Q. When the stages of the river are equal, the fact is that the current of the Mississippi overcomes the current of the Missouri and turns it down at right angles, and runs it along the Missouri shore?

A. Yes, that can happen. It does hapen.

Q. But at the same time there is more or less a mixture of each of the rivers on the Missouri shore at St. Louis, at the Chain of Rocks?

A. Sometimes this mixture which may be found in the channel may crowd over toward the Missouri shore somewhat, but still our analytical data show that samples taken close to the Missouri shore will always be prevailing Missouri river water, if close to the Missouri shore.

1413 Before the Mississippi and Illinois meet there is a long narrow strip of land that divides them, and when they meet they run almost parallel; that is, they come together slowly. The Illinois river water keeps close to the Illinois shore. It is entirely a different situation than that at the mouth of the Missouri. The place where the samples were taken at the Chain of Rocks was left very much to the judgment of the collector.

Q. There was then, as to the Missouri shore, no fixed and certain place at which the samples was taken?

A. No, sir, it depended upon the current entirely and it was left to the judgment of the man who took the sample as to where he should take it.

1414 Q. So that a sample one day might have been taken 300 feet from the Missouri bank, and the next day 1,000 feet from the Missouri bank?

A. Yes, sir, if the current would run that way; he was instructed to get samples accordingly. The current of the Missouri at the Chain of Rocks on the Missouri shore is constant and regular. It varies somewhat in volume and in the width of the current at that place, but there is always
1415 some Missouri river current water running close to the Missouri shore. Our analytical data shows that. I could not tell from the analytical data alone whether a sample was taken within three hundred feet of the Missouri shore line or whether it was taken from about nine hundred feet from the Missouri shore line.

1417 Q. Do you suppose that any of the water which you took at the place which is designated as the Illinois shore ever got into the intake?

A. Yes, it got into the intake quite frequently.

Q. Well, how did it do it?

A. Well, when the Missouri river was low, and the larger volume of the Mississippi river water coming down the Illinois shore would push the Missouri river toward the Missouri shore and beyond the intake, which is 1,500 feet distant from the

Missouri shore line, and on such days the Mississippi and Illinois mixture water would get into the intake.

Q. Now let us see if we can understand each other. The point on the Illinois shore opposite the Chain of Rocks, and the point at the intake tower and the point which you designate as the Missouri shore, constituted a cross-section of the Mississippi river?

A. They were to constitute a cross-section as near as possible.

1419 Q. The water at the Illinois shore at the point at the Chain of Rocks, and at the point from which you took it, never did get into the intake, did it?

A. It could not on such days because the point of collection was to be far enough away from the intake so that it should not be water that was going into the intake, but should be water that was passing along the Illinois shore.

1421 Q. Take your chart 8, for instance, and tell me whether or not you base your calculation as to the percent of chlorine at the intake tower upon the 23d day of January upon the data which that table or chart shows?

A. Yes, based upon the chlorines there I made an approximate estimate there, and an approximate average of the per centages as found at the Missouri shore, Illinois shore and the intake tower, at the Chain of Rocks.

1422 The waters at the point called the Illinois shore do not turn a right angle and make a straight shoot for the intake tower.

Q. What point up the Mississippi river do you think that it would be fair to select in order to get a sample of Mississippi river water which actually intermingled with the Missouri and went into the intake tower?

A. I consider one mile above the mouth of the Missouri river in the Mississippi as a proper point.

Q. Well, then your calculations as to the pollution of the waters of St. Louis having been based entirely on the samples taken at the Illinois shore, are upon a false basis, are they not?

1423 A. I cannot say that they are on a false basis because they have not been compared in such a way.

Q. Where did you obtain data upon which you base the calculation made as to the percentage of Mississippi river water and Missouri river water entering the intake tower?

A. One sample was taken from the Missouri river at Ft. Bellefontaine; another sample from the Mississippi river one mile above the mouth of the Missouri designated as Hartford in the analytical records; the third sample was taken from the collection point at the intake tower. The samples from these three points were compared. The residue on evaporation was selected as affording the widest range in figures, and therefore the closest approximate estimate of percentages of mixtures at the intake.

Q. What percent of what proportion of the water taken at Hartford of the entire water, was Illinois river water at that point you don't pretend to know?

1424 A. Well, by inspection alone I could not ascertain that chemically that water was a mixture, it required the chemical analysis subsequently made to determine that Illinois river water was contained in the mixture running in the channel.

1428 If I find by analysis that the water going into the intake tower has a higher per cent of pollution than the water of the Missouri river at Bellefontaine, my chemical conclusion is that the water going into the intake tower is very largely Mississippi river water. My conclusion is based not upon any ability to observe by the currents, which river it is, but solely and entirely from the chemical analysis.

1429 Q. Why, in order to determine the respective quantities of Missouri and Mississippi river water pumped, did you take a sample from the Illinois shore when you knew it was a physical impossibility for that water to be pumped at all?

A. Well, that is to show the character of the current running down the Mississippi river at the Chain of Rocks.

1431 Q. Was chart 8 made for the purpose of showing that the water at the intake tower was intermediate in its quality, as between the Missouri river and the water on the Illinois shore?

A. In so far that the study of the analytical data proved that, yes.

As to chart 9, my data as to typhoid wer obtained from the Health Commissioner's office of St. Louis. My instructions were to take them from the official reports.

1433 Can you explain why the typhoid fever in St. Louis did not visibly increase from March 20 to August 14, 1900?

A. In February, the upper Mississippi above the mouth of the Illinois was low. The water then represented in the mixture at the intake—I want to say that evidently there was a larger percentage of Illinois river water, of that mixture going into the intake in February and being represented by a high percentage, one day as high as 100 per cent, going down again and then going up again, in February, up to 90 per cent; there was more Illinois river in that mixture; that was followed by a rise in typhoid for the month of March.

Q. Now, why did the typhoid fall and the percentage of cases fall when the Mississippi river was at 100 per cent on the 27th or in the middle of April?

1434 A. Because then at that time the Mississippi river water had a different character than the Mississippi river water coming down in February, and it had a larger per centage of upper Mississippi river water and a smaller per centage of Illinois river water.

Q. So that the chart doesn't contain anything about the Illinois river, but simply assumes that when the typhoid fever is bad, the Illinois river water prevails.

1435 I have ascertained that a large majority of the cases of typhoid fever in St. Louis reported during one year after the opening of the canal, that these cases all correspond with the fact that the patient had been drinking city water during that period. I got this from the official reports of the physicians when they reported their cases to the health department.

1436 These reports show that in some instances they have been drinking milk. There are about 3,500 or 4,000 wells in St. Louis. There are quite a number of cisterns in addition to that, so that we usually say there are 7,000 cisterns and wells in the city of St. Louis. It was ascertained in this special investigation that of the 1,160 or 1,180 cases reported in 1900, of typhoid, three-fourths of these patients did not drink any well water or cistern water, but only drank water from the city supply.

CROSS-EXAMINATION by Mr. Todd: These 1,180 cases were cases reported by the physicians of St. Louis to the Health Department—not deaths. The number of deaths in 1900 was over 100.

1438 There has been typhoid fever in the city all along every year—the statistics will show some typhoid.

1439 Have been connected with the Board of Health of St. Louis for ten years. There was a letter sent out to the physicians in the city asking them to report typhoid cases coming under their immediate care in the fall of 1900 and another one issued in the fall of 1901.

Q. Previous to the one issued in the fall of 1900, do you know of any letter having been sent out to the physicians in St. Louis during your term in connection with the Health Department of the city of St. Louis?

A. There wasn't exactly a letter sent out, but I remember as long as I have been connected with the health department that the Health Commissioner has frequently requested physicians through the press and in official reports, to report the number of typhoid more promptly.

1440 Q. Well, that letter stimulated the doctors in reporting cases of typhoid, didn't it?

A. Well, it called their attention to the violation of that law in not reporting cases.

1442 There were more cases of typhoid in 1899 than 500; that is during the entire year. Typhoid was very low, but during one month they went up some.

That increase in typhoid was in November, 1899.

1443 Q. The Drainage canal had not been opened then?

A. That I couldn't tell.

1445 I do not consider myself a medical expert on typhoid.

Q. Can you as an expert in chemistry attribute any part of the 1,180 cases in 1900, to the opening of the Drainage canal?

A. Indirectly, yes; in connection with my statements. I consider it in a measure as very striking that with the increase in the pollution of our water supply, and the increased pollution of the DesPlaines river from the Drainage canal, and the Illinois river and the Mississippi down to the intake in the year 1900, I consider it very striking that there was corresponding with that increase in pollution in the month of March, 1900, an increase in typhoid of 1,300 per cent over the average of the five preceding years for the number of cases in St. Louis.

1446 A person not a chemist nor an expert on typhoid could draw the same conclusions if he would give the matter as careful study as I have tried to do. During the five years previous to 1900, the water supply of St. Louis as found in the hydrants, was not good, potable water. It required boiling, and filtration.

Q. Now, do you compare potable water or drinking water as being bad or worse?

A. I do compare the analytical results in 1899, prior to the opening of the canal. I compare those results with those of 1900, 1901 and 1902, after the opening of the canal, and the water has become worse in its chemical character since the opening of the Drainage canal.

1447 Q. But before that it wasn't drinkable, was it?

A. Frequent warnings were issued by the Health Department and myself to boil the water or filter it well before drinking. Those instructions were given because the water was not found to be potable. The water as it existed today, if filtered or boiled would be as good as the water that existed prior to 1900 if boiled or filtered. The Health Department of St. Louis has advised the citizens not to drink the water of St. Louis since 1893.

The water as proved to be prior to the opening of the Drainage canal, was polluted. The analytical results showed pollution in a measure from sewage and in a measure of vegetable origin.

Q. Where did the sewage come from that got into the water of St. Louis?

A. In my opinion, as a result of my investigation in 1899, I found that the Missouri river and the Mississippi river above the mouth of the Illinois were of much better sanitary quality than the Illinois river at the mouth of the Illinois, and I found at that time that the Illinois river polluted the Mississippi river after meeting the Mississippi river and that this pollution extended along the line or along the route of the Mississippi river as it came down and passed the intake, or at times when the Missouri river was low, it would go into the intake. At that time the Missouri river water was potable.

1448 Missouri river water is now potable water. In this case I testified as a chemical expert who is supposed to make himself familiar with all the bacteriological features connected with the chemistry of water. Chemically, I am prepared to say the waters of the Missouri are potable. But bacteriologically, I am not prepared to answer the question. The water

1449 of the Mississippi river above the mouth of the Missouri was not potable prior to the opening of the drainage canal.

1450 I am prepared to say that (prior to the opening of the canal) 75 per cent of the daily quantity of water going into the intake would be Missouri river water, and about 25 per cent would be Mississippi river water.

Q. Would the amount of Mississippi water entering the intake be sufficient to keep the water supply of St. Louis in a polluted condition?

1451 A. As I stated in my testimony in direct examination, prior to January, 1900, the water supply of St. Louis as coming from the water going into the intake, was potable at times. I said in my conclusions there were great variations, and at some times the water would be a good drinkable water, the water would be potable, and at other times it would be very bad, polluted, as I said. (Witness states on page 1447 that the water was not potable.)

1452 Above Grafton, the water of the Mississippi river prior to 1900 was potable.

1453 The Illinois is prevailingly a slow river, sluggish current. Its current is supposed to be slower than the Missouri and Mississippi and the results of examinations as published demonstrate that. The volume of water coming down the Illinois varies greatly. Sometimes may amount to 1,200 cubic feet per second and then it may be 112,000 cubic feet per second. The volume of the Mississippi never goes down to 1,200 cubic feet per second from what I have studied about it.

1454 The Illinois river water, as it runs along the Illinois shore, is stopped by dikes, and it is kept in the corners of the dikes, and only a part of that water is gradually, when the upper rivers rise, swept out, and gets into that narrow channel, so that the identity of the Illinois river, as such, would, in my opinion, be lost before it reaches the intake.

1457 Took samples from DesPlaines river in October and November, 1901. From the analyses made of those samples I considered that water potable water.

1458 I mean by that good drinking water. I know that some towns drain their sewers into that river. I do not know that the waters of the DesPlaines river have been condemned by the Board of Health of the city of Chicago as being contaminated and that ice men are prohibited from selling the ice from that river.

1459 Q. Then if the sewage of these different places that I have indicated, (Riverside, La Grange and Maywood,) (Riverside being ten miles away), does empty into the Des Plaines river, and did empty at the time that you made your examination, purification of that sewage had been completed at the point that you made the examination. Is that correct?

A. Yes, sir; if the facts are such; provided, however, that the volume of water was sufficient, and the DesPlaines river at times can discharge as much as 600,000 cubic feet of water per minute.

Q. And assuming also that the sewage from these points above there was emptied into that river, before that sewage got to the point that you took your samples, it had been purified, and the water had been rendered potable, according to your anaylses, is that correct?

A. Yes, my analyses established the fact that during those two months the water taken from the DesPlaines river was potable before it reached the Drainage canal.

1460 Q. The principles of purification will apply to the Des Plaines river the same as to any other river, would they not?

A. Well, if the conditions were alike, of course.

1463 There is no general theoretical principal that sewage contaminated water from cities above, receiving an additional discharge of sewage from cities below, that the water of the river so contaminated at the time of the additional discharge will retard the purification of the stream. It all depends upon the practical results.

1464 Q. Is there any principle established by chemical science that holds the river would not purify itself of sewage that it has received?

1465 A. I don't know of any as applied to those conditions prevailing in the Mississippi river above the mouth of the Illinois.

At certain times during the year the water of the Mississippi river above the mouth of the Illinois, from three to five miles above the mouth of the Illinois, that water is potable; at other times it is not potable. It varies according to the amount of impurities. During the warmer period of the year the water from that river is always better than it is during the winter months.

1466 June, July, August and very often we have summer weather prevailing through the month of September.

1467 The potability increases in the spring slightly with the warm weather.

Q. Does the rain-fall in July affect the potability of the water in the Mississippi river above Grafton?

A. Assuming the weather is warm, certainly warm temperature will assist materially in purifying—it assists in making it potable.

1468 Q. Doctor, if the waters at Grafton were chemically decided to be potable, is not the conclusion irresistible that the sewage, however magnified or increased in the upper Mississippi has been purified by the time it got to Grafton?

A. It would demonstrate that the pollution of the Mississippi river above Grafton is of such a character that it does not affect the potability of the water of the Mississippi at the mouth of the Illinois.

Q. And how is that question of potability arrived at aside from the theory that running water purifies itself in a certain distance if the analysis of the water demonstrate beyond question that the waters at Grafton are potable? (Taking into consideration the fact that St. Paul, Minneapolis, etc., discharge their sewage into the Mississippi.)

1469 It is possible that such purification may take place, but it is necessary for various conditions all to co-operate to being favorable to such a result being obtained.

1473 Q. Now, if the water of the Mississippi river at Grafton is potable, doesn't it convey to your mind, as a chemist, that sewage discharged into that water at Minneapolis and St.

Paul and all the cities nursing the banks of the Mississippi river, has become purified to the degree of potability by the time it gets to Grafton, the point where you made your examination?

A. Stating as I have done, that I am not familiar with the conditions, whatever pollution there might have taken
1474 place in that Mississippi river above the mouth of the Illinois river, whatever pollution has taken place, it has been rendered sufficiently harmless by the time that water reaches the mouth of the Illinois as to render that water potable during certain times of the year, as I have stated. My opinion is that practically throughout the year the water of the Mississippi river above Grafton is permissible as good drinking water.

Assuming Grafton was a large city and I was placed in charge of the water supply of that city as a scientific man, I would consider that water from the Mississippi river potable and would advise the citizens of Grafton to use the waters of the Mississippi river above the entrance of the Illinois river for drinking purposes during those eight months without boiling and without filtering.

1477 The bacteriologists who hold that sewage polluted streams are not potable water, the views of those learned men, meet with the approval of my judgment.

1479 Q. Now if a condition of that character presented itself to you where a stream was chemically potable and bacteriologically contaminated, what would be your opinion as to the potability of the water?

A. If such a condition should exist—I don't know of any—if it should exist, that water would certainly from a general hygienic standpoint, not be considered potable because the bacteriological pollution would certainly stamp it as unpotable, as not potable.

1481 I adopt the rule that all sewage contaminated streams are not potable, but I do not accept it as a hard and fast rule for every possible care, disregarding entirely the various conditions that should come into consideration. It is possible that the rule may be applicable to the Mississippi river above Grafton, providing that the conditions prevail that will justify its application. I do not know whether those conditions prevail or not. I don't make the Mississippi river an exception to that rule. I can not tell whether it comes within that rule unless I make an examination of the conditions necessary to form an opinion.

1483 I have examined both conditions chemically and bacteriologically and thereupon formed a conclusion that the water of the Mississippi is potable three and five miles above the mouth of the Illinois. I did not make a personal analytical examination at the points above indicated, neither did I make a bacteriological examination. I do not know from my personal knowledge whether the waters at that point were bacteriologically pure, or not.

1484 The information I have has been reported by bacteriologists who made examinations at that point.

Excluding the opinions of everybody and basing my opinion upon my personal knowledge I cannot say that the waters of the Mississippi river three miles above Grafton are potable bacteriologically and chemically, that is, based upon personal analytical investigation of my own, so that when I testify as to the potability of these waters, my answer is based upon my personal research as a chemist. If the bacteriological information that I base the final conclusion on, is erroneous, I would certainly modify my views accordingly.

1485 I have no opinion of any bacteriologist who holds that the waters of the Mississippi above Grafton are potable. I form my own opinion from the study of analytical data.

1490 If Dr. Ravold drew the conclusion that the waters of the Mississippi river were not potable at Grafton, I differ with him in his conclusions, that is, viewed from a general hygienic standpoint.

1492 I consider the waters of the Missouri river potable at Ft. Bellefontaine, the station in the Missouri river where we collected samples of water. Bellefontaine is five miles above the mouth of the Missouri. The water is more or less potable all the year around. It varies according to the seasons.

1493 I would consider the water found at Ft. Bellefontaine station potable throughout the year to a varying degree. *Sioux City* empties its sewage into the Missouri river. So does Omaha. Omaha has large packing industries and large distilling interests. Across the river from Omaha is Council Bluffs, which is quite a manufacturing town.

1494 They discharge their sewage into the Missouri river. So does St. Joe, Leavenworth, Atchison and Kansas City. Kansas City has great industries in the packing and slaughtering business. It has distilleries, too.

MR. JEFFRIES: I object to all the questions and move that they and the answers be stricken out.

1495 The sewage of Jefferson City empties into the Missouri river. So does Herman, Missouri and St. Charles, Missouri. The reason the Missouri river at Bellefontaine is potable, when all these cities and towns that have been mentioned here empty their sewage into the Missouri river, depends very much upon the amount of sewage which these cities discharge into the Missouri river. It depends furthermore upon the volume of water in the Missouri river. It depends also upon the velocity of the flow, the general conditions of the course of the Missouri river, what accessions of soil in the form of clay and silt the Missouri river takes along its winding course and what effect sedimentation of this enormous quantity of soil will have on the sanitary character of the water. There are various conditions that obtain in the Missouri river that do not obtain in the Illinois river.

1496 The water in the Missouri river is generally larger. The courses that the Missouri river takes is one of a great many bends and curves, much more so than the Illinois river. There are, as I have said, enormous accessions of soil swept along the course of the river from the shores of the river into the Missouri river. This is not the case in the Illinois river. Heavy sediment of clay will produce at such points along the river where the velocity is slow, particularly if there are many bends and curves, considerable sedimentation along the banks. The Missouri river overflows and this overflow will cover vast areas of land sometimes. This helps the purification because sedimentation, according to the accepted axiom of modern science, will assist materially in purification. These conditions prevail from my own observations along the Missouri river between Kansas City and St. Louis.

1497 Between Kansas City and St. Louis I might have seen ten square miles that were overflowed, but I could not say positively that it was that much. Since these conditions prevail along the route between Kansas City and St. Louis from information that I have I should think it would have a considerable effect in the purification of the Missouri river.

1498 Q. Is there anything else more beneficial for the purification of that stream than that?

A. It has a character of great stability which I would distinguish as a chemical characteristic. Stability in contradistinction from instability would be that the processes of purification have reached the stage where the final product of the nitrifying cycle, that is, the oxidation of the free ammonia to nitrites and nitrates has reached a stage so that it is largely completed as is always evidenced in the Missouri river between those points that I have mentioned, by low nitrites, and uniformly low nitrites between Kansas City and St. Louis and comparatively high nitrates. I do not know how far below Omaha and Council Bluffs the water becomes purified and potable after the sewage has been emptied into it. As regards the point of purification, the question could not be answered.

1499 Because the conditions are such in the river that while the water in the channel below Omaha might show chemical improvements after the sewage of Omaha has been discharged into the river, the water running along the shore line would not show that to that extent. Because it is a well known fact that the sewage from cities is discharged on the shore. It flows along the shore where there is supposed to be a current of less velocity than the current in the channel. The sewage may appear in this shore water whereas the channel current is entirely different water. It does not get into the channel until at high stages of the river when flood water comes down. The serpentine course of the Missouri river would not necessarily serve to get the sewage in the channel. It would be impossible for me to say that the sewage would be purified 20 miles down from Omaha.

1500 If the sewage should be placed in the channel sometimes it would take longer to purify it than it would along the shore on the banks, because it would depend somewhat upon the character of the water, the velocity of the stream and the character of the water the velocity of the stream and the character of the sewage being flushed from the shore into the channel.

1501 It would take longer for the sewage in the channel to purify than it would if it remained in a quiescent stage in the overflowed banks along the shore. The conditions in the channel of the Missouri river are such that usually when the sewage of the cities is flushed into the channel that it has previously undergone a certain stage of preliminary purification along the shores in the sediment of the banks which are overflowed at those points in this poorly regulated river.

1502 I know that it is a fact—I have obtained it from analytical data from those points. I have never seen the sewage of Omaha and Council Bluffs when it entered the Missouri.

1503 At that point I could state it is a theory. At Kansas City I investigated the conditions there but I have not seen the sewers myself. It is a theory justifiable from analytical data obtained. As to Kansas City I have no personal knowledge based upon observation as to how the sewage enters the Missouri river, nor as to Leavenworth and St. Joseph. I have not seen the sewer outlets of any of these places with my own eyes. If you define it as personally known to me (as to how long the sewage remains along the banks instead of entering the channel) I say it is a theory.

1505 I have no opinion based upon scientific data as to how long it would take the sewage from Omaha, Council Bluffs, Kansas City, St. Joseph or Leavenworth to purify itself. I have no opinion in regard to any of the cities located upon the Missouri river as to how long before the sewage from such cities would purify itself, if emptied into the channel.

I have a reason why the water at the point of Bellefontaine
is potable, based upon investigations I made of the Missouri
river. Those are the great length of the river, its many
1506 curves and bends, its many sedimentation beds along its
course and the long time water takes to flow all this distance
from Kansas City. The distance from St. Louis to
Omaha by the water line of the Missouri river is 676 miles; to
Kansas City it is 403 miles; from Omaha to Kansas City is 273
miles. The character of the sewage entering the Missouri river
at Kansas City is a sewage very high in percentage of refuse
matter from slaughtering houses and rendering establishments
and it contains 60 per cent of the sewage of Kansas City as discharged
into the river. This sewage, of course, includes the
fecal matter, it includes all the dirt in the streets as
1507 swept into the sewers from rainfall or from street
sprinkling. There is considerable sewage entering the
river from slaughter houses and other manufacturing establishments.

Q. Does that sewage from Kansas City purify itself in the Missouri in going 400 miles?

Objection by Mr. Jeffries.

A. Whenever sewage pollution has taken place from the sewage of Kansas City, that sewage pollution has to such an extent disappeared when the water reaches Fort Bellefontaine, after a run of 403 miles, that water is potable at Fort Bellefontaine.

1508 In a normal stage I am of the opinion that the Missouri river is slightly swifter than the Illinois. When the Missouri river is low and the Illinois river is low, the velocity of these two streams would be about alike. The average velocity of the Missouri river would be from three to three and one half miles.

1509 I have been at times on the Illinois river when the current was one mile and then again, when it was declared to be two miles, but not from my own investigations. At times, at high water, I have known that it was three miles an hour. The current can go up, at high water, in the Missouri, to four miles an hour.

1510 It is very likely that I have analyzed waters taken from the river at Bellefontaine when the current of the river was four miles an hour.

Q. How can you state that the waters of the Missouri river all the time are potable, in view of the fact that when the current of the river is four miles an hour and it is only 403 miles from Kansas City to St. Louis, which at that rate would be four days for the sewage to get from Kansas City to St. Louis, that the water is potable?

A. I can only form the conclusion that the water is potable, from the chemical analyses performed upon the water taken from the Missouri river at Fort Bellefontaine and the water was potable.

1511 Q. If your analytical data is correct, would not it justify the conclusion that when the current of the river is four miles an hour that it will purify itself in running a distance of 403 miles?

A. I can not draw the conclusion that sewage will purify itself in four days' running, because it can not be ascertained whether it came down in four days.

1518 In my examination at Fort Bellefontaine I found albuminoid ammonia in the waters of the Missorui river.

1519 The albuminoid ammonia in comparison with the free ammonia was considerably high. That indicates contamination of organic matter. If albuminoid ammonia is found in suspension more than in solution it will indicate organic matter due to contamination of vegetable origin.

Q. Why not animal origin, Doctor?

A. Because the organic contamination of animal origin is more represented in the albuminoid ammonia in solution. Because the organic matter of animal origin that is found in solution in the albuminoid ammonia will represent to a large extent the pollution of animal origin in soluble forms. If the albuminoid ammonia is in solution instead of suspension to a high degree that will enable the conclusion that the origin of the organic matter may be more from animal sources.

Q. In what condition would you find the albuminoid ammonia from the sewage of slaughter houses—in suspension or solution?

A. Well, in both, very likely. In suspension would prevail the more largely. I found considerable high albuminoid ammonia in the Missouri river at Bellefontaine. It was partly in suspension and partly in solution.

1520 At times the albuminoid ammonia in suspension would be larger than the albuminoid ammonia in solution and at other times the reverse would show.

Q. If that is true, how would you distinguish between the albuminoid ammonia of vegetable and animal origin?

A. The distinction could be made from that point of view that the organic matter in suspension is very largely composed of such matter as is of vegetable origin.

The albuminoid ammonia found at Bellefontaine, Missouri, for a larger part of the time appears to be in suspension and the smaller part in solution.

1521 Organic matter is the origin or albuminoid ammonia, that organic matter may be from animal and it may be from vegetable origin.

Q. Is albuminoid ammonia derived from vegetable, the same ammonia that is derived from animal?

A. Well, as a product of distillation it is the same. There are no identifying characteristics of albuminoid ammonia when it is found, that will enable the chemist to say whether that ammonia came from vegetable or animal origin, if he bases his opinion solely upon the product of distillation.

1522 There is nothing in the albuminoid ammonia itself that will enable the chemist to ascertain whether it came from animal or vegetable origin, that is, not in the analytical product itself. In the Missouri river I found albuminoid ammonia in solution and in suspension in different degrees.

Q. When albuminoid ammonia is found in suspension does that indicate whether it is of animal or vegetable origin?

A. Well, that could not be determined from the analytical product itself.

Q. If albuminoid ammonia was in solution would that indicate whether it was from vegetable or animal origin?

A. Not if determined as found from the analytical product itself.

1523 When this albumen which we denominate albuminoid ammonia becomes disintegrated by bacteria or oxidation it gives what is known as carbonate or chloried of ammonia. Then when the free ammonia by similar processes of oxidation or bacteria is broken up, it results in what is known as nitrites and the nitrites by similar process change into nitrates, the final product in the cycle of nitrification.

Q. So that in the beginning is what is known as albuminoid ammonia or albumen in the process of fermentation or purification?

A. Yes, probably carbonate of ammonia and chloride of ammonia, but including of course these almubinous compounds.

1524 Albuminoid ammonia is present in the sewage from slaughter houses and fecal discharges from man and animal. It is also found in the decomposition of vegetable matter.

Q. Doctor, as a chemist, do you enunciate as a principle of chemistry which you yourself by your analytical investigations have established, that albuminoid ammonias in suspension indicate vegetable origin, and albuminoid ammonias in solution indicate animal origin?

A. I said that they may be present in both; not altogether in one.

I can differentiate between albuminoid ammonia of vegetable origin and that which is of animal origin by taking into consideration the oxygen consumed results, which enable, in a measure, an opinion as to the vegetable or animal origin.

1528 Q. Can you tell from the presence of nitrites whether the nitrites come from vegetable or animal origin?

A. I could only take the general results of the entire analyses and certain local conditions as they are prevailing at the point where the sample is taken.

Q. That is, if you knew, independent of chemistry, that the water was sewage contaminated from the sewage of man or animal, then the nitrites appearing there, you would draw the conclusion that they came from animal rather than vegetable origin? Is that correct? A. Yes, sir.

Q. If you did not know the origin but only had the nitrites to go upon, could you tell whether it was of vegetable or animal origin?

A. No, sir, not if I took the nitrite results by themselves, I could not do it.

1529 I can not tell by the presence of free ammonia in itself whether it is of animal or vegetable origin, nor of nitrites,, nor of nitrates. Nitrates come from nitrites and nitrites from free ammonia; free ammonia comes from albuminoid ammonia.

1530 High chlorines in a river may indicate sewage pollution and they may indicate the passing of the river through a deposit of salt in the geological structure. It is uncertain what it indicates for chlorines alone.

1531 The sewage from all the cities upon the Missouri river entering into the Missouri river carries with it sodium chloride and in addition to that, I have testified about the Kaw river. As a chemist I can not distinguish the sodium chloride which comes from sewage and that which comes from the beds of the Kaw river, as I have testified.

In a measure, I took into consideration, in drawing my conclusions as to the conditions of the Missouri river as to its potability, the sodium chloride which entered that river from the sewage of all the cities along it. There is a certain amount of chlorine found in the Missouri river above the mouth of the Kaw river. The analyses show that and also a certain amount of chlorine is found in the Missouri river after the Kaw river empties into the Missouri river. When it got to Bellefontaine, I was not able to state what percentage of the chlorine I there found came from the sewage, and what percentage came from the Kaw river, whether the percentage from the sewage was larger than the percentage that came from the Kaw river, I am not able to ascertain chemically.

1532 The conclusion is justified that since the average chlorines are uniformly higher between Kansas City and Bellefontaine, that since as much as 100 parts per million, or five and six times as much chlorine is found in the Kaw river, that the Kaw river certainly is responsible for the high chlorine prevailing between Kansas City and Bellefontaine, as compared with the chlorines between Omaha and Kansas City.

The Kaw river enters the Missouri above Kansas City.

1533 The Kaw river chlorines show 100 parts per million.

The Missouri river after the Kaw river discharges into it may not show more than 24 parts per million of chlorine and above the Kaw, it might be 16, that would show an increase in the chlorines of the Missouri river resulting evidently from the mixture of the two rivers. The samples I took in the Missouri river were taken below Kansas City, that point had received the sewage of Kansas City, in addition to the volume of water from the Kaw river.

1535 The sample that was taken above Kansas City was taken above the mouth of the Kaw river.

1536 Took three samples all together below Kansas City, Missouri. The sample that I took above the Kaw river in the Missouri river showed on the day of collection, 16 parts per million of chlorine. The sample taken in the Kaw river showed on one day 100 parts per million of chlorine.

1537 The Missouri river sample below Kansas City showed 24 parts per million of chlorine. Above Kansas City showed 16 parts per million, which shows an increase of one-third in the chlorine. Since that day the Kaw river showed very high chlorine—80 to 100 parts per million—the conclusion could be drawn that so much chlorine coming from the Kaw river into the Missouri river would affect the quantity of chlorine found in the Missouri river below Kansas Ctiy.

1538 Q. Doctor, in the absence of the known volume of the Missouri and of the Kaw, do you take into consideration the sewage contamination from Kansas City, Missouri and Kansas City, Kansas, as to the chlorines?

A. Well, I didn't in this case. I admit that a definite conclusion could have been drawn if the quantity of chlorine coming from the sewage into the river could have been ascertained, but that is an impossibility and, on the other hand, the Kaw river showing such tremendously high chlorines, I considered it a natural conclusion that there must be some effect of the high chlorines in the Kaw on the increase in the Missouri river.

1539 I eliminated from my opinion or conclusion, the volume of water in the Kaw, the volume of water in the Missouri and the sewage of Kansas City.

1540 The volume of water in the Missouri above Kansas City varies considerably. It may be 100,000 cubic feet and it may be 600,000 cubic feet per minute. I have no accurate data as to the Kaw, nor as to the volume of sewage that enters the Missouri river from Kansas City, Missouri and Kansas City, Kansas, except that I have ascertained from the city engineer of Kansas City, Missouri, that only 60 per cent of the population drain sewage into the river directly. In order to draw a conclusion as to whether the chlorine below Kansas City comes from the sewage of Kansas City, Missouri and Kansas City, Kansas, or from the Kaw river, it is important to know the volume of the Kaw and the amount discharged into the Missouri from those cities. Such knowledge would enable an absolutely accurate estimation.

1541 Q. Your conclusion then is not accurate, is it?

A. Well, I consider it an approximation. If the Kaw river was only a river of two or three hundred cubic feet per second, emptying into the Missouri with the volume I have indicated, that would dilute the chlorines in the Kaw flowing into the Missouri enormously. Those very analyses I presented show that they are reduced from 100 in the Kaw to 24 parts per million in the Missouri, which is an enormous dilution. I cannot say what proportion of the increase of chlorine below Kansas City is due to the Kaw river and what to the Kansas

City sewage. I don't know whether 90 per cent of it is due to the sewage or not.

1543 Q. Doctor, why didn't you take into consideration the sewage from Kansas City in your conclusions in regard to chlorine?

A. I had no available data. I could not obtain them. It would have necessitated an investigation which I could not undertake at that time.

1544 In none of my investigations have I taken into consideration the sewage discharge of Kansas City, in calculating the chlorines for the Missouri river. It was because I could not obtain the data that eliminated the sewage of Kansas City entirely from my consideration. I relied upon the condition of the Kaw river as found, to justify the approximate conclusion.

1545 Q. Then you don't know what proportions of the chlorines below Kansas City came from Kansas City and what came from the Kaw river, do you?

A. Not from any investigation of the Kansas City sewage.

1546 Q. Now the chlorines that you found at Bellefontaine, you are unable to say what proportion of those comes from Kansas City sewage and what porportion comes from the Kaw river?

A. I feel justified, when the Missouri river is low and I find high chlorines at Ft. Bellefontaine that those chlorines can come from the Kaw river chlorines largely, if not altogether.

Q. Assuming that 90 per cent of the chlorines found at Bellefontaine comes from the Kansas City sewage, would that have any effect upon the potability of the waters of the Missouri river?

A. Not unless corresponding high nitrites and correspondingly high free ammonias would be shown.

Q. If correspondingly high nitrites and correspondingly high free ammonias were shown and the albuminoid ammonias you were not able to ascertain whether they were from animal or vegetable origin, could you tell?

A. And how much chlorine would be in that calculation?

Q. The amount which you found by your analyses. Would you denominate that water potable?

A. If the nitrites, chlorines and ammonias were high and I was personally convinced that the chlorines were due to sewage and not from the Kaw river, I would say, according to the axiom of sanitary science, that the water was not potable.

1548 Q. If the albuminoid ammonia should be of animal origin and accompanied by high nitrites and nitrates and free ammonia and high chlorines, the water would not be potable, would it?

A. It would not, if accompanied by those other high ingredients you mention.

1549 You could have high ammonia in solution and in susnever found high nitrites in the Missouri river. The nitrates are high.

1552 Q. Now, if you have got high albuminoid ammonia, free ammonia, low nitrites, high chlorines and you do not know what the source of that chlorine is, would you say the water was potable, or not?

A. I would base my judgment upon the conditions prevailing and the source of that high chlorine.

1553 I would refuse to give an opinion without that information. The waters of the Missouri river at Fort Bellefontaine are what is known as stable waters. The term "stable" is applied to a river where the fermentative changes and the nitrification changes which the impurities in the river undergo are more of a uniform character and are going on in the manner that they do not change rapidly and where analy-
1554 tical results show by uniformly low nitrites that the cycle of purification has reached a stage where a large portion of the impurities have been converted into nitrates, the final product of the cycle of nitrification.

1554 I found the albuminoid ammonia in the waters of the Missouri at Bellefontaine quite high. I found the free ammonia as a rule, which I consider low, but at times I found a slight increase in the free ammonia, where I would say that the free ammonia was there in a considerably quantity. The nitrites I found uniformly very low for a river. The nitrates I found at times quite high. The chlorines I found high, sometimes as high as 46 parts per million. The Missouri river was a polluted stream at Fort Bellefontaine based upon my chemical analyses.

1555 Its pollution is variable, you could not define it. That is, you could call it a polluted stream. I would not call it a very polluted stream. I attribute the pollution to organic matter of vegetable and animal origin, the degree of each varying. I am approximately able to state from my analyses the extent of pollution attributable to vegetable origin and to animal origin. Applying the same principle in determining the vegetable origin of the organic matter, I would say that whenever the albuminoid ammonia in solution runs very high with the organic matter—as estimated by the oxygen consumed process—high and the nitrites, although uniformly low, would still show their presence by a figure showing that there was still fermentative changes going on at that time—at such times I would say that the pollution could be of animal origin. At such times the water was not potable.

1556 The conditions I have just described would obtain during the winter months. Absolutely considered as winter months, I would consider from three to four months. During those four months this condition of pollution that I have described as being attributable to animal origin obtains in the Missouri river.

1557 During that time the waters of the Missouri are not potable.

Q. Then when you stated in your testimony yesterday that the Missouri river was potable throughout the year, you eliminated from your consideration the four winter months, during which animal contamination existed in the Missouri river?

A. I am very glad that you brought that matter up, because if I said "throughout" I did not mean to say that. What I meant to say was, "prevailed during the year," in taking the larger part of the year when I think the water is potable but for those four months I do not consider it potable. As to the other eight or nine months of the year when I claim the water is potable, that condition was ascertained by chemical analyses. I have supplemented my chemical analyses by bacterial investigation. The waters of the Missouri river are not bacterially pure. The bacilli coli communis I consider are found in smaller quantities in the Missouri river during those summer months than in the winter months.

1558 The presence of bacilli coli communis may indicate either sewage pollution, if corroborated by chemical analyses or may indicate fecal discharges of fish. There are many fish in the Missouri river. Since investigations have determined that fish have in their fecal discharges the colon bacillus, and if the chemical analysis does not demonstrate sewage pollution of the waters, the conclusion may be reached that sewage not being identified as present by the chemical analyses, the presence of the bacilli coli communis may be ascribed to the fecal discharges of fish. It is some time ago since I have studied data and reports on such investigations and at this moment I cannot remember whether it has been proven that bacilli is present in fish in streams other than sewage contaminated.

1560 Outside of the data secured from Dr. Ravold I have not made any independent investigations on the line of bacteria in the Missouri river. From the data compiled by Dr. Ravold, I consider the Missouri river potable during these eight or nine months that I have specified as representing the warm season of the year—potable at Fort Bellefontaine.

1562 The Missouri river at various points is sewage polluted wherever the sewage enters the river from cities along the line.

Q. Do you know of any scientific man who has investigated the waters of the Missouri, who holds to the doctrine that it is potable, aside from yourself?

A. Well, if I understand the testimony of Prof. Keiser correctly, he testified to that effect. From a bacteriological standpoint alone, a running river should not be judged as to its potability. The chemical condition should be taken into consideration. I do not know of any other authority on bacteriology who holds that the Missouri river is potable.

1564 Q. Assuming that the conditions existed at Bellefontaine as you found them, by your analyses, and that the high chlorines that you found there were attributable to the sewage discharge of Kansas City, what would be your conclusions as to the stability of the Missouri river at Fort Bellefontaine?

A. Even if those high chlorines you mention there were due to the sewage from Kansas City, after a run of 403 miles, even then it would be very difficult to ascribe such character to the water as you hypothetically present to me as due to sewage pollution from Kansas City, for various reasons—first of all, the distance from Kansas City to St. Louis would be 403 miles by water. Only 60 per cent of the Kansas City sewage would go into the Missouri river. The Missouri river during its winding course, with many curves, there being no dams or anything, the river overflowing frequently during its course, carrying a great deal of sewage over vast places adjoining the river, and at a low stage of the river, as the river falls, much of this sewage never coming down the river, being left there in a condition of fermentation, on that soil, previously overflowed. It would be impossible to claim that any Kansas City sewage reached St. Louis or reached Bellefontaine.

Q. Then the conclusion is irresistible that the sewage of Kansas City has become purified before it reaches Bellefontaine, in going a distance of 403 miles?

A. At certain times, when all of such conditions would prevail as I describe, I would say yes.

1565 The distance that the stream would purify itself from Kansas City would depend upon the velocity of the current and the condition of the river itself, that is, in enabling the overflow over large banks. It is a uniform rule that the waters in the Missouri, with the higher stage of water, have a swifter current in the channel.

1566 The lower stage of water, the slower the current.

1567 I cannot tell how far above Bellefontaine the water purifies itself of the sewage of Kansas City.

1568 I know from the official statement of the city engineer of Kansas City that 60 per cent of the sewage of the population of Kansas City, Missouri drains directly into the Missouri river. I have no information about whether the sewage from the cattle and stock yards is included in the 60 per cent population.

1570 The time it takes nitrites, by the process of oxidation to become nitrates would depend upon the number of aerobic bacteria in the water.

1571 If the waters contain large quantities of bacteria the time would be lessened. In laboratory experiments we find that the nitrites found present in the respective samples of water on the first day disappear after a number of days and the nitrates increase showing that nitrites have been converted into nitrates.

Q. Supposing that there would be a great number of aerobic bacteria present in the water and the nitrites were not in a large quantity, how long would it take?

A. This process would be a very rapid one. It might take 24 hours and it might take 48 hours for a small amount of nitrites to disappear. If the aerobic bacteria were present in the running water in great numbers that would have a tendency to decrease the nitrites even in the water.

1574 The presence of clay and silt in water is evidence of a greater number of these bacteria that possess the nitrifying effect upon the nitrites. The conclusion is justifiable that they are there in great numbers. There are more nitrifying or so-called oxidizing aerobic bacteria in the Missouri river water than in the water of the Mississippi and that, of course, would accelerate the oxidizing action in that water.

1575 The laboratory experiments show in the analytical results of water of one sample collected day after day from the same original sample that the changing of the ammonia into nitrites is slow, that is, the reduction per day of ammonia in quantity as estimated by analyses was very small, whereas the reduction of nitrites was large and small amounts of nitrites would, as I said, disappear in a period of from 24 to 48 hours. The samples taken at Fort Bellefontaine arrived at the laboratory three or four hours after they were taken. The nitrites were determined immediately upon arrival of samples.

1577 Q. Can you state, Doctor, as a positive fact that the low nitrites which you found in the waters of the Missouri at Ft. Bellefontaine are not attributable directly to the action of these bacteria from the time of the taking of the sample up to the time of the analysis?

A. If such a reduction of nitrites to nitrates, or rather oxidation—to be absolutely scientific—if oxidation of nitrites to nitrates took place in those samples while they were in transit from the station at Fort Bellefontaine to the laboratory, it would be so inappreciable that it could be disregarded because of the fact that the samples were packed in ice and kept at a very low temperature from the time they were collected until the time the chemist would take the sample, open the bottle and make his nitrite test.

Q. How do you know that, Doctor, as a scientific fact, is applicable to the waters of the Missouri?

A. From comparative tests that I made on a boat analyzing samples for nitrites probably ten minutes after they were taken from the place of collection and analyzed on the boat, and comparing the result with samples packed in ice and taken to St. Louis and analyzed. From these tests I have come to the conclusion that the oxidation of nitrites is inappreciable for six hours at times and other times, at eight hours, if the samples were properly packed in ice.

1578 These were Mississippi river samples; they were not Missouri river samples. There were no bacteriological approximations made on the number of aerobic bacteria from these samples.

1580 I made no investigation in any of my analyses for the presence of aerobic bacteria in the waters of the Mississippi. The oxidation of nitrites depends upon the presence of these bacteria. If this bacterium is present in large quantities oxidation will be facilitated provided there is also a large quantity of dissolved oxygen present in the water. There may at times be more dissolved oxygen found in one river than there is in the other.

1582 I have never made an examination of the waters of the Missouri river at Fort Bellefontaine at the time they were taken out of the river.

1584 In making my analyses I looked for causes so far as the water is concerned, on the route between Chicago and St. Louis. As regards Fort Bellefontaine samples, I only looked for the condition of the water at Bellefontaine and did not look for the causes.

1585 I don't admit sewage pollution at Fort Bellefontaine from Kansas City or the stock yards.

1586 I looked for causes partly during that period when the investigation showed pollution at Fort Bellefontaine. I considered it my duty to ascertain what this pollution might be ascribed to.

Q. Then your answer to my previous question that you were looking for effect and did not take into consideration the causes, you wish to modify, do you?

A. That is to be applied to that period when I found that water good and potable, then it was unnecessary to look for any cause but during that period of the investigation when I would find the Missouri river water polluted, I made an effort to ascertain the causes of that pollution.

1587 When I found the water pure or good at Fort Bellefontaine I did not look for the causes which created that good condition of the waters. I was mindful all the time in my investigations that the sewage of Kansas City, Missouri and Kansas City, Kansas, and the other towns located upon the Missouri river was emptying into the Missouri river. As long as I found the water good, I did not look for the causes that purified the water from the sewage contaminations of the cities above.

Q. Are you able to state what made the waters good, with the knowledge that there was sewage pollution at Kansas City and at other points?

pension in the Missouri river from vegetable origin. I

A. Nobody could state that. That is impossible.

Q. Then that is a matter outside of the realm of scientific research?

A. No, sir. I can not name anybody who could tell. Scientific men give an explanation from stating the general conditions in the Missouri river between Kansas City and Bellefontaine.

1588 It is problematical.

Q. But it is not problematical what becomes of the sewage of Chicago, is it doctor?

A. The Chicago sewage is entirely different.

Q. Has the light of scientific truth shone more clearly upon the chemical and bacteriological mind in regard to the Chicago sewage than that of the Kansas City sewage?

A. The conditions of the two rivers are so materially different, the quantity of sewage coming from Kansas City being discharged into the river is so materially different from the sewage being discharged from Chicago into the Des Plaines river, the conditions of the Des Plaines river and the Illinois river vary so much from the conditions prevailing in the Missouri river. The distance between Chicago and St. Louis for

the sewage to run is 357 miles and the distance from Kansas City to St. Louis is 403 miles, making 46 miles difference.
1591 I have estimated in volume the sewage discharged from
Kansas City, Missouri and Kansas City, Kansas, by usual or customary calculation.

Q. After you find that out, what use did you make of it?

A. Well, I studied the conditions of the Missouri river and I utilized the data in the customary way such conditions are studied.

1592 Q. Why didn't you take into consideration in ascer-
taining the source that chlorine came from the sewage of Kansas City, Kansas, and Kansas City, Missouri, when you made the test below Kansas City?

A. Because it is difficult to estimate from the volume of sewage discharged into that river the quantity of chlorine.

Q. How much of the chlorine that you discovered in your analyses below Kansas City was attributable to the sewage of Kansas City, Kansas, and Kansas City, Missouri?

A. That is a question which I yesterday answered that I could not tell, because I had not made investigations as to the quantity of chlorine to be found in the sewage discharged from various outfalls into the Missouri river because of the extreme difficulty in ascertaining the amount of chlorine there. The amount attributable to the Kaw river would vary much. It depends upon the volume of water in the Missouri.

1593 Q. Is there anything in connection with the chlorine
itself that will enable you to tell whether it is mineral pollution, as evidenced by the discharge of the Kaw, or sewage pollution as evidenced by the sewage of Kansas City, Kansas, and Kansas City, Missouri?

A. Yes, sir. As I explained yesterday, the fact that the analytical results of the water at Fort Bellefontaine do not show correspondingly high free ammonia and chlorines and nitrites together, and that the nitrites are uniformly low
1594 is no justification to ascribe the high chlorines to sew-
age pollution.

Q. The question is, is there anything in the chlorine itself?

A. No, sir.

Q. Then the only reason that you attribute the presence of chlorine at Fort Bellefontaine to the Kaw river and not to sewage is based upon consideration aside from the chlorine itself?

A. No, sir, in determining that question it is necessary to take into consideration the general analytical results as found from the analyses of the samples at Fort Bellefontaine. If the chlorine is due to sewage pollution there should be high nitrites, high free ammonias and high organic matter would show in the results. If the nitrites are low and the free ammonias low as it usually is in the Missouri river this high chlorine cannot be attributed to sewage pollution. It must come from mineral matter, it must come from salt. The determination of the sources of chlorine must be had from outside considerations, aside from the chlorine itself and that determination is based
largely on low nitrites, high free ammonias and high
1595 chlorines. I believe I stated that albuminoid ammonia
would come into consideration as organic matter either
high or low. If the free ammonia were low that is the most essential point involved there. The free ammonia for the major part of the year is very low in the Missouri river. The nitrites are either very low or absent entirely.

Q. Assuming that the general analytical results show albuminoid ammonia, free ammonia, low nitrites, chlorines in the amount that you found it, but that the chlorines were attributable to sewage pollution and that there was no river
Kaw?

1596 A. Well, if it would be an established fact that the
chlorine was due to sewage pollution, why that water in itself would be unpotable because of its sewage origin. If the chlorines were identified as coming from sewage pollution, the presence of the other ingredients going with it would of themselves form a part of that conclusion, because the fact is then established as such that the chlorine is due to sewage pollu-

tion. In making the nitrite test, alum was added to the
1597 water to clarify it. After the addition of alum, the water was filtered. I have known that the waters were
1598 potable since 1899. I have always been an advocate of using Missouri river water for consumption in the city. I have agitated the use of the Missouri river water in preference to that of the Mississippi at the present intake. I first entertained those views in regard to the Missouri water being the best water to be used in the city of St. Louis in 1899. I first became connected with the city as chemist in 1893. At that time I knew of the contemplated building of the Drainage canal.

1599 Q. From 1889 on to 1893 or 1894, was anything said about the canal and its construction in the papers of St Louis that you know of?

A. Yes, sir. The matter was discussed in the year 1893 to some extent. It was a matter of general knowledge in St. Louis that this improvement was being made in Chicago. It came up before the Board of Health in the form of a discussion of a resolution introduced in the year 1893. I believe the Health Commissioner of St. Louis at that time—Dr. George Homan—introduced the resolution. One resolution in 1893 was that in view of the construction of the Drainage canal at that time going on in Chicago, a National Board of Experts should investigate the question as far as it would affect the water supply of St. Louis and questions in general pertaining to sewage pollution. The Board of Health recommended in the resolution either that Representative Barthold of St. Louis, in Congress, should introduce a measure asking for such an investigation, or that such a measure had already been introduced by Mr. Barthold and was supported by this resolution. The other resolution was calling upon the city chemist to perform some analyses of water. He was to collect them from the mouth of the Illinois down to the city of St. Louis at that time, from the Mississippi river and the Illinois river.

1600 I don't recollect whether the recommendations of the Board of Health made to the Mayor of St. Louis for an injunction suit in the Federal Courts against the construction of the Drainage canal whether that was the result of the analyses that I made of the water or whether it preceded this investigation. I cannot recollect at this time because it is nearly ten years ago.

Objection by Mr. Jeffries.

I made a cross-section of the waters in the Mississippi river above Grafton. I did not make a cross-section of the waters of the Illinois river before the same entered into the Mississippi river at Grafton. I made a cross-section of the Mississippi river below Grafton, at Alton and at Hartford.

1601 Five samples were taken at Alton in that cross-section. That is, whenever a cross-section was taken, five points were selected in a line across the river and the samples taken at that point. The number of days when these cross-sections were taken cover about a month—every day. The samples taken at Alton were practically taken during the same months and days that the samples were taken at Hartford. There were a few samples taken at one point I believe which the record will show. They cover the same period of time in both places. It was the month of November, 1901. I also made a cross-section at the Chain of Rocks, St. Louis waterworks. 12 samples were taken across the river on five different days from November 25 to November 30. There were some cross-sections taken from the Illinois river at points betwen Peoria and Pekin and at Pekin. No samples were taken at the mouth of the Illinois river for cross-sections.

1603 At Fort Bellefontaine on the Missouri two cross-sections were taken. Eight samples were taken across the river November 29, then again on the following day on November 30, another cross-section was taken at Fort Bellefontaine. There was no other place in the Missouri river that samples were taken in cross-sections. Alton is 16 miles below Grafton. Hart-

ford is 14 miles below Alton, and nine miles above the
1604 Chain of Rocks. The distance between Pekin and Grafton is about 140 miles. Cross-sections were taken at Pekin bridge on November 12, 16, 19, 23 and 26, 1901, two samples on each day.

1605 Q. Now in order to ascertain between the 25th and 30th of November, at the Chain of Rocks, the component constituents of the waters of the Mississippi as to whether the water there was Missouri, Mississippi or Illinois water, you would be confined to the data from the period between November 29th and 30th, would you not, as those are the only two days that the cross-sections were made in the Missouri river?

A. Well, if the conclusions to be derived from the analytical data would depend upon the cross-section—

Q. Well, doesn't the conclusion which you arrive at depend upon the cross-sections?

A. That depends upon conclusions in what respect, because I—

Q. As to the character of the waters at the Chain of Rocks in the Mississippi river?

A. Not altogether.

Q. Then what was the purpose of taking 12 samples of water across the Mississippi river at the Chain of Rocks, between the period of November 25th and November 30th daily?

A. I said that it was not dependent altogether upon those cross-sections, but the cross-sections of course gave me certain information that I wanted to obtain from the cross-sections in order to obtain facts that the cross-sections would reveal to me.

Q. Well, when the cross-sections failed to reveal the facts that you were looking for, would you go anywhere else for those facts? A. Yes, sir.

Q. Where would you go?

A. Well, I would take all the analytical data that I could obtain on that qusetion and consider them from a general standpoint as every chemist would.

1606 And what were you trying to prove by cross-sections,—these waters mixed and went into the intake?

A. Yes, sir.

Q. And if these cross-sections did not reveal that fact, then you went elsewhere to find that fact to prove that they mixed and went into the intake, did you?

A. Well, I said in connection with the general analytical result, I would take the result of the cross-sections and consider them.

Q. But you would not consider them by themselves, would you?

A. Not in determining that question entirely. I would take into consideration the total solids, which total solids were not estimated in these cross-sections that I looked for.

Q. If this cross-section made at the Chain of Rocks, at Hartford, Alton, Bellefontaine and at Pekin did not prove conclusively to your mind that the waters of the Illinois river entered the intake of the city of St. Louis, did you go any where else for any facts in order to establish that fact?

A. Well, in reviewing the analytical results from these cross-sections my views were strengthened as to the currents coming down the Mississippi at the Chain of Rocks.

Q. Then before you made these cross-sections you had views that the waters of the Illinois entered the intake tower of the city of St. Louis, did you not?

1607 Yes, sir. These cross-sections were made to confirm that view as far as nitrites and chlorines could confirm that view, because I only took cross-sections for that purpose. These conclusions that I drew were to my mind sufficiently definite to dispense with a further investigation of that problem. Those cross-sections did not establish independently the fact that the Illinois river went into the St. Louis intake. I had formed an opinion on that question prior to the taking of the cross-sections.

1608 In the Missouri river I only took two cross-sections on November 29th and 30th.

Q. Wouldn't it be fair to limit your investigations in the cross-sections at the Chain of Rocks in ascertaining the St. Louis water, to November 29th and 30th?

A. No, sir, that wasn't necessary because I had practically formed on opinion as to that question prior to the taking of those cross-sections.

1613 On the 29th of November the Missouri river itself would press the waters of the Mississippi toward the Illinois shore by the time it got to the Chain of Rocks. It will always push the water somewhat toward the Illinois shore because of the manner in which it comes down the Missouri river and during a larger part of the year this volume being quite large, it would press the Mississippi river somewhat toward the Illinois shore, it follows that if the pressure is very great and the volume of the Missouri river very large and the volume of the Mississippi river not so large, that the pressure of the volume of water would push the Mississippi so close to the Illinois shore that on such days nothing but Missouri river water would enter the intake at the edge of the channel in the Mississippi.

1614 At other times, the condition might be the reverse and then the intake being located 1,500 feet from the Missouri shore, would receive at that time nothing but Mississippi river as it comes down the river. There has been a sand-bar formed in the Mississippi river just above the intake. It can happen that the water would sweep around that sand-bar and I have seen considerable of an angle, and be pushed over toward the Missouri shore.

Q. And keep the Missouri river towards the Missouri shore?

A. Yes, push it a little more toward the Missouri shore because this water at an angle, it would come around that sandbar with considerable pressure and would press the Missouri closer toward the Missouri shore. At such times, the water in the intake would be from the Mississippi.

1615 The analytical results of samples taken at Hartford and Alton in the Mississippi river as compared with the results of samples taken at the Illinois shore opposite the intake always show by comparison somewhat less in impurities in the sample of the Illinois shore at the Chain of Rocks. That would show some mixing effect of the Mississippi and Illinois rivers at the point on the Illinois shore if the sample was taken opposite the intake.

Q. Have you made any calculations of the percentages of decrease in nitrites of the waters of the Illinois from Grafton down to Alton, in going that distance?

A. No, but there is invariably a decrease noticeable in the analytical results of the nitrites found at Alton as compared with the samples taken from the Illinois river at Grafton.

1616 Q. Do you attribute that to the mixing of the Mississippi or to the natural fermentative changes that take place in the water?

A. I think that it may be due to either cause. It is difficult to determine to which cause in all those instances it would be due. It may be due to either and the same is true for the sample found at the Illinois shore at the Chain of Rocks. I have not made an analysis of the waters of the Illinois river for a distance of 39 miles immediately above its mouth to Grafton. I do not know how much the varying changes would be for the samples taken 39 miles above Grafton on the Illinois river.

Q. Do you know whether it would be any greater than is evidenced by your analysis from Grafton to the Chain of Rocks along the Illinois shore?

A. I don't think the change would be so great in the Illinois river from the point 39 miles as you state.

1617 On what do you base that, doctor? Have you made any experiments of it?

A. Because of the fact that the Mississippi river connects with the Illinois river at Grafton and that the Missouri river connects with the Mississippi river at the mouth of the Missouri. That would change the conditions materially and bring about a different situation than exists in the Illinois river between the point 39 miles above Grafton and Grafton. I do not know what perçentage of Mississippi water and Illinois river water is in the channel of the Mississippi river at Alton. There would be a way of ascertaining it. By comparing the general analytical data I formed the opinion that there is some mixture taking place in the channel.

1618 I thought approximations would suffice for the purposes of my investigation. The same condition obtained at Hartford. I made no investigation to ascertain the amount of Illinois and Mississippi river water at Hartford. When I got to the Chain of Rocks I could, by approximations, form a conclusion as to the relative mixtures there prevailing at the Chain of Rocks.

Q. Could you take a gallon of that water in the channel of the Mississippi river at the Chain of Rocks and tell how much of that water was Missouri river water, how much Illinois river water and how much Mississippi river water?

A. No, sir, not that way.

Q. Could you anyway?

1619 A. I could by careful study of the analytical data obtained from anaylses of samples taken in the Illinois river a few miles above Grafton, above its mouth, samples analyzed as collected from points in the Mississippi river at Alton and Grafton, from the analytical data obtained from samples in the Missouri river. I have done that.

Q. Well, will you tell me what are the parts of those three rivers making up the channel of the Mississippi river at the Chain of Rocks?

A. It is impossible to make these approximations without carefully studying for every case.

Q. You have done it, then?

A. I carefully studied these analytical data. I have done so, yes, sir.

Q. Can you give me the result of your investigation?

A. No, sir. I have not those data at hand. I have done it though, taking the analytical figures.

1620 This is an approximation as applied to the different waters in the channel of the Mississippi river at the Chain of Rocks.

1622 Q. Can you mention any of the substances in the sewage that is discharged into the Drainage canal at Robey street, which are in themselves harmful to health, whether in large or small quantities?

A. Well, the analyses of the samples taken from the Drainage canal at Robey street show certain chemical conditions—the chemical analysis I am referring to now—showed certain chemical conditions of that sewage if confined to the chemical conclusions would not justify me in saying if anybody would drink that water in the Drainage canal at Robey street, after that sewage would have entered it, that it would be injurious to his health, as far as the chemical constituents are concerned, but that leaves out of the question all the bacteriological character of that sewage. There is a question of the potability of that water. It may not show any chemical ingredients that would injure anybody who drinks that water. You can drink sewage—what you call pure sewage, although impure, and there may be no pathogenic bacteria in that sewage and it may not do you any harm.

1623 The chemical analyses alone would not reveal that there are any substances in the sewage discharged into the Drainage canal at Robey street that are dangerous to health.

1624 From the tables that have been prepared on bacteria and introduced in evidence I would draw the conclusion that they disclose pathogenic bacteria as being present in the sewage at Robey street in the Drainage canal. This pathogenic bacteria is coli communis. I consider it in a measure a pathogenic bacteria. Some intestinal diseases are ascribed to the presence of soli communis.

1625 There is abundant evidence that they are found in the intestinal tracts of many individuals.

Q. Is it not a fact, doctor, and recognized by bacteriologists everywhere that the bacilli coli communis is non-pathogenic?

A. There are some authorities who will call it non-pathogenic because in many individuals it is harmless and then again, there are others who call it pathogenic because it is harmful to others.

Q. Is it not a fact, doctor, that the only way coli communis becomes harmful is when it is inoculated into the blood or into a cut and not harmful when it is taken into the alimentary canal?

A. Well, some authorities assume that standpoint. I am not an expert bacteriologist.

1630 I have not made an accurate scientific estimate of the extent of organic pollution from the Peoria distilleries and glucose works. In my investigations I took into consideration the sewage conditions of Peoria. I gave this pollution which is mentioned some consideration.

1631 The composition of the sewage from the distilleries of Peoria is a certain swill of organic matter that is cast off as refuse.

1632 This material will, in the course of time, undergo some certain chemical changes and will disappear in the run of the river into which it is discharged. I could not tell whether it will oxidize more slowly or more rapidly than household sewage.

Q. If it disappears rapidly, does it disappear more rapidly that household sewage?

A. That I could not tell.

1633 At places where the discharge is in such large quantities as in the Illinois river at Peoria and Pekin, my own eyes have shown me this swill and refuse from the distilleries. I have seen it anumber of miles down the Illinois river.

1634 Seventeenth annual report of the Health Commissioner of the city of St. Louis introduced. In 1893 by authority of the St. Louis Board of Health, I made analyses of the Illinois river. I started with the collection of three samples on October 11, 1893, at points one, three and five miles above the mouth of the Illinois.

1635 These samples were taken on one occasion only. I did not take any other samples until September, 1899.

Q. Now in the examinations that you made of the waters taken in 1893, what was the condition of the waters of the Illinois river?

A. The results showed the presence of organic matter as evidenced by free and albuminoid ammonia; the presence of nitrites to some extent and the presence of high chlorines, proved contamination of the Illinois river at the mouth.

Q. By sewage pollution?

A. Well, since only one set of samples was taken on that day and I thought that a longer series of collections should be made, I did not pass any definite conclusion at that time on the character of that pollution. In 1899 when I made examinations of the waters of the Illinois river I did draw the conclusion from the large number of samples collected that there was considerable pollution of the Illinois river at Grafton. I stated at that time that the pollution found in 1899 was of a character indicating sewage pollution of the Illinois river. One of the conclusions was that the Illinois river at its mouth was badly polluted during the entire period of investigation, from September, 1899, until the middle of January, 1900, before the opening of the canal.

1637 Q. And in that investigation, did it demonstrate conclusively the character of the pollution as to whether it was sewage or vegetable?

A. My opinion was that it was sewage pollution.

Q. Sewage pollution? A. Yes, sir.

1638 In my investigation in 1893, I found high albuminoid ammonia. I did not determine at that time the albuminoid ammonia in suspension or solution. Free ammonia was comparatively low and the nitrites were quite high in the Illinois at that time. I would not say high, but quite high, the intermediate between low and high. The chlorines were very high. In my examination of 1899, I found the albuminoid ammonia, the free ammonia, the nitrites and the chlorines to be quite high and at times again, low. Albuminoid ammonia I found comparatively high in solution. In suspension I did not find it as high throughout as I did in solution.

1639 I found the albuminoid ammonia in suspension, as compared with the albuminoid ammonia in solution lower that the albuminoid ammonia in solution, but the albuminoid amomnia in suspension was high also aside from being compared with that in solution. Sometimes it would be high but for most of the time the albuminoid ammonia in solution would be higher.

1640 During 1899 I found sometimes the free ammonia low and then again I would find it high. The nitrites the same way. The chlorines I found pretty high. From that analysis I concluded that the Illinois river as it enters the Mississippi was a sewage contaminated stream and the waters were not potable taking into consideration the reports of Prof. Long and Prof. Palmer as to the condition of the entire Illinois river valley. Taking into consideration all the information that I had at hand, I concluded in 1899 that the Illinois river was a sewage polluted stream and was not potable water. I am not acquainted with what is known as Lake Joliet, south of Joliet along the line of the Des Plaines river.

1641 Q. If Lake Joliet was two or three miles in length and from one-half to a mile in width, with a kind of peat bottom bogs, and the waters passing through would disseminate themselves throughout the lake and would only leave a slow current through the lake, would not that act as a sediment basin for the waters of the Des Plaines river?

A. It would somewhat, and the slower that current would be, the more sedimentation would take place. The faster the current would be, the less the sedimentation would be. A great proportion of the sewage going through a lake of that character would have a tendency to be deposited on the bottom of such lake or morass as it were and fermentative changes would operate in a lake of that character.

1642 Q. If it should appear, doctor, that before getting to Lake Joliet there were quite a number of acres of land over which the waters of the Des Plaines flowed, sedimentation would take place under those conditions the same as it would in the lake, would it not?

A. Yes, if the current were very slow and these low lands would retain any of the sewage that had been during the overflow deposited on the banks. If such conditions would prevail, these fermentative changes would be facilitated somewhat.

Q. While the waters were over the land would sedimentation be the only method of purification?

A. Well, since sedimentation would be one of the material forces of nature, that would bring about various stages of what we call purification. It would operate as a septic tank, for the ordinary conditions that are requisite for a septic tank would prevail there. As I said, slow flow and an abundance of anaerobic bacteria to perform the initial process of purification. I would consider a slow current a current that would have perhaps one-eighth or one-eighth of a mile flow per hour. If the current should be as high as half a mile per hour that would have some effect in facilitating sedimentation.

Q. After the waters left Lake Joliet on their way down the Illinois river, if it should appear that thousands of acres of land were inundated, low-lands, over which the water in its course traversed, what effect would that have upon the prification of the sewage laden waters of the Des Plaines river?

A. It would have some effect in distributing the sewage over vast fields there, during the overflow, and if the sewage would have some time there to remain in a quiescent state some fermentative changes would take place in the ordinary process of purification.

1643 If after traversing over these many acres of land that were inundated, it finally empties into the Illinois river, where it continuously overflows the banks of the stream in high water, that condition of purification would be facilitated whenever conditions of inundation of large areas of land would prevail.

Q. Do you know what the conditions are through which the Des Plaines river runs, from Joliet to La Salle, on the Illinois?

A. I am familiar with the conditions somewhat. I have no data or idea of the number of acres of low land between those points that the sewage laden waters of the Drainage canal run over in arriving at La Salle.

Q. Have you any idea or any information of any kind in regard to those conditions?

A. I have nothing definite in that direction.

Q. Don't you think that in order to properly consider this question intelligently, data of that character is essential? A. No, sir.

Q. Isn't it as essential to know in the Illinois river as in the Missouri?

A. It is a matter of analytical investigation as far as the character of that water is concerned, in considering the question of sewage pollution of those rivers, and if the analytical results show high figures at various points along the route that the river is traversing, it would be the most important information, and if found consecutively along the entire route, it would justify general conclusions as to the character of that water chemically.

Q. Wouldn'e it be essential, doctor—as essential in ascertaining the origin of contamination as to whether from vegetable or animal, to know these conditions obtaining in the Illinois river betwen La Salle and Lockport?

A. It is not necessary when the analytical data from the samples taken along the route demonstrate high pollution because the object of the analytical investigation is only to ascertain the character of that water as it flows along that route.

Q. Have you not repeatedly stated in your examination, doctor, that the anlaytical data, in the absence of knowledge as to the source from whence pollution came, was not sufficient to enable you to determine whether it was sewage or animal pollution? 1644

A. The source, yes, of the pollution as estimated in the analyses of the samples.

Q. And have you not stated that large areas of overflowed land eliminated sewage contamination from waters?

A. I said that it may do so under certain conditions.

Q. And is it not necessary to ascertain whether those conditions exist or not, before drawing a conslusion as to whether the elimination or the presence of the chemical constituents of the water are attributable to animal or vegetable origin?

A. If the analytical results uniformly show high impurities along the route of a river, there are various questions that come into consideration, such as the original source of that pollution, the relative proportion of pollution that might come from tributaries, the relative proportion of pollution that might come from large cities that discharge their sewage into that river. Those questions of primary importance would be considered and in explanation of the origin of the pollution if the chemical analyses enable an approximate distinction between vegetable and animal origin of the organic matter, it would be sufficient to form final conclusions on the character of that water as it traverses the route of the river.

Q. Did you ascertain all those conditions that you have enumerated?

A. In application to what investigation do you mean?

Q. Illinois river?

A. Illinois river, you mean after the opening of the Drainage canal? Q. Yes? A. Yes, sir.

Q. What tributaries of the Illinois river did you investigate for sewage pollution?

1645 I investigated practically all the tributaries that may come into consideration in determining that question. I did not make any analytical investigations of my own because I found such data published by responsible authorities, by Professor Long and Professor Palmer, that could be taken as a fair criterion for the character of those rivers and also a report published by Lyman E. Cooley in 1890.

1646 I understand that there is a large stagnant pool in excess of a mile right under the hill at La Salle. If the Illinois river there would stop its flow completely and enable sedimentation by the stagnant condition of the river there, fermentative changes producing initial purification would certainly be facilitated. I have no idea how many thousands of acres of land in the form of marshes are along the course of the Illinois river. I understand that inundations take place at times of overflow by the Illinois and Des Plaines rivers before the waters get to Peoria. Purification and sedimentation would take place on these overflowed lands the same as would take place along the shore of the Missouri river if conditions were alike in both rivers. Those conditions are, first of all, the chemical character of that water, carrying the sewage. The quantity of the sewage in that water in proportion to the quantity of water with which it is mixed, the weather conditions and several other conditions as I have explained them before, which would facilitate the fermentative initial purification process.

1647 That part of the sewage, however, that would remain in the channel would not be similarly affected. That part of the water that would overflow those areas of land would be

come impregnated with vegetable matter. What it would lose
in sewage pollution it would gain from vegetable pollution to
a certain amount. If that land had vegetation it would neces-
sarily receive accessions from that source. Vegetable pollu-
tion would manifest itself in the presence of albuminoid am-
monia and also in the color of the water and sometimes as found
in the odor of the water. Lake Peoria is located above Peoria.
When the waters pass into Lake Peoria after coming from Chi-
cago over vast swamps and marshes, through different lakes
and stagnant pools, Lake Peoria would continue the fermenta-
tive changes and oxidations of that sewage water more or less
dependent upon the size of that lake and dependent upon the
question whether there is a flow in that lake, any current carry-
ing the water through the lake rapidly and so forth. I made
no investigation to ascertain the dimensions of Lake
1648 Peoria. I don't know how large Lake Peoria is nor how
swift the current is. I don't know the source of the
Kankakee river. I know of the Kankakee marshes of Illinois,
from literature published on the subject. If it should appear
that those marshes drain into the Kankakee river, the Kanka-
kee river would carry into the Illinois large quantities of pollu-
tion due to vegetable origin at times of very high water in the
Kankakee. I deem it a matter of considerable importance to
know the number of acres of land in the form of marshes that
the waters of the Illinois commingle with and overflow before
arriving at Peoria.

1649 I tried to obtain all the information from available data
published. I did not get any specific information in re-
gard to the number of acres of land along the Illinois river that
was overflowing marshes or farm lands, except that there are
general conditions which I familiarized myself with from the
literature published on the subject. The dam at Henry is locat-
ed above Peoria. At times the flow of the Illinois river is very
much retarded at that dam as well as at the other four principal
dams which are located in the Illinois river. The retarding of

the flow of water at these places serves to elevate the water and back it up stream and overflow the banks of the river and on each side of the river at those places the land is low and thousands of acres of land are inundated by virtue of those dams. Those conditions, in a measure, act as a septic tank for the waters of the Illinois when it is backed up there and held by those dams. I didn't in my examinations endeavor to ascertain in what measure and to what extent purification would take place at those points.

1650 I think I was able to judge from analytical results from the samples taken along the route what effect the dams would have in the ordinary purification processes of the sewage in the water. I think that at times during the year some effect is due to those dams in purifying these waters of the Illinois river to some extent. That effect would be prevalent during the low water stages of the year, after the overflow had taken place, carrying the sewage laden water over those fields. That is, at the low water stage that part of the sewage that would remain on those fields would not be swept back into the river and of course the low water stages then would facilitate the purification processes.

1652 Q. During high water, there is increased dilution with a correspondingly increased current, with a correspondingly greater area of territory inundated, is that true?

A. Yes, sir. These elements may be of value but not essential in drawing a conclusion as to the sanitary character of that water as it flows in the river.

1653 I have not taken into consideration all those conditions.

Q. Would you be able to draw a definite conclusion from the analyses in the absence of any knowledge upon those conditions—a conclusion as to the condition of the water and the source of its contamination, whether vegetable or animal?

A. Yes, as far as that is concerned.

Q. Take the chlorines—could you tell to what the high chlorines would be attributed in the Illinois river if you didn't know the source from which it was derived, except by the analyses that were made of the waters?

A. These high chlorines and the high ammonias and the high organic matter in general found there, if accompanied by high nitrites would suffice to enable the conclusion that the chlorine there was due to sewage pollution. The conditions of the Illinois are different from the conditions of the Missouri.

Q. Can you tell by the chlorines whether in the Illinois river they come from vegetable or animal origin?

1654 A. Well, that would be impossible for anybody to determine as to the chlorine itself. As chlorine, I cannot tell whether it comes from mineral, vegetable or animal origin. It is not likely that you can have free ammonia, high albuminoid ammonia and high nitrites from vegetable origin. It may be possible. I think it does in exceptional cases, but not as a rule. Those conditions can not obtain in water from animal origin unless accompanied by correspondingly high chlor-
1655 ines. You could have high free ammonia, high albuminoid ammonia and high nitrites with the chlorines attributable to salt beds. You could have that condition as being derived from vegetable origin.

1656 That may be possible in some instances but it would be an exception to the rule.

1661 Q. At what times would these rivers (tributaries of the Illinois) pollute the waters of the Illinois so as to make the waters of the Illinois unpotable.

A. Well, they could do so when the stages of the river, by its tributaries, would be high, because that would sweep out whatever accretions of pollution there might have been on the banks, that would increase the ammonias. It would sweep out the deposited sludge in those rivers and that would enter the rivers. Now this would depend very much upon the character of that pollution, whether of vegetable or animal origin. I speak of pollution in general—not specifying sewage pollution. The general analytical results from those rivers demonstrate that the pollution from those tributaries disappear during the run of the Illinois river. I think that the Joliet sewage before it would reach the mouth of the Illinois would be purified to the extent that the effect of the original pollution would be of a character that while the water at the mouth of the Illinois would be pure, yet it would it would be in a much better condition than the water at the mouth is, because of the sewage of the drainage canal entering the Des Plaines river.

Q. I am eliminating the drainage canal, doctor. I am taking conditions that are based upon the elimination of the sewage of Chicago? A. Yes, sir.

1662 That would be true of La Salle and the towns located along the river there. If the water of the Illinois river when it reached the city of Peoria would be pure, it would be true that the sewage of the city of Peoria would chemically have undergone changes by the time it reached Grafton to the effect that it would not be noticed in the analytical results found in the water at Grafton, chemically speaking.

Q. Now, doctor, if your statements are properly based upon investigation and if you properly state the conditions of the Illinois river and its tributaries, as to pollution, will you explain to me how it was in 1899, before the opening of the Drainage canal, you reported to the Board of Health of the city of St. Louis, that the waters of the Illinois river at Grafton were contaminated, and not in a potable condition as evidenced here, by the report on file?

A. Because I found the water of the Illinois river above Peoria badly polluted.

1663 My chemical analyses of the samples taken in the Illinois river a few miles above Grafton demonstrated the polluted character of the river at that point and my investigation of analytical data furnished by Prof. Long and Prof. Palmer showed that the Illinois river was badly polluted a few miles above Peoria.

Q. Then if your conclusions are correct that the Illinois river was a badly polluted stream in 1899 throughout, why is it then that you conclude that the sewage of the cities along the banks and its tributaries do not contaminate the waters of that river at Grafton?

A. Because the Illinois river was badly polluted before it reached Peoria it passes those towns and simply assumes its bed character again. The Illinois river could be badly polluted and yet any pollution from the tributaries and the towns along the Illinois river could be so inappreciable that it would not materially affect the character of that river. The river in its entire course was polluted in 1899.

Q. The sewage of Chicago previous to the opening of the Drainage canal did not enter the Illinois river, did it, or the Des Plaines river?

1664 A. Yes, sir, it did.

Q. Havn't you testified that when the sewage from the Illinois and Michigan canal was pumped into the Des Plaines river that it had been operated upon by conditions such as a septic tank would give and that the sewage had almost disappeared?

A. Yes, I consider that the preliminary stage of purification had been greatly facilitated by the conditions prevailing in the Chicago river and in the Illinois and Michigan canal but I never claimed that it was not sewage any more when it was discharged from the Illinois and Michigan canal into the Des Plaines river and the Illinois river at La Salle. Why, that is still sewage as long as it is not purified in its entirety and has reached the final stage of nitrates. It is my conclusion that the Illinois river was polluted by the sewage from the Illinois and Michigan canal to some extent in 1899 certainly, and the analytical data show that. It manifested itself at Grafton by the bad condition that the water was found to be in at that point.

1665 Previous to the opening of the Drainage canal the amount of sewage entering the Des Plaines river through the Illinois and Michigan canal could not very well be estimated but the chemical analyses can show the presence of characteristic ingredients of sewage pollution that would enable an estimate of the degree of pollution of the water in the Illinois and Michigan canal with the sewage. An accurate count has been kept and published of the number of gallons pumped from the south fork of the Chicago river into the Illinois and Michigan canal at Bridgeport. The amount that is pumped each day indicates the amount of sewage that enters the Illinois and Michigan canal. It varies considerably, sometimes it may be 10,000 or 12,000 cubic feet per minute and other times, it may be 20,000 and 30,000 and as much as 40,000 cubic feet per minute.

1666 I could not tell how that compares with the amount of sewage from Kansas City, Missouri, at that time.

1667 My opinion, based upon my knowledge of the conditions prevailing in the Illinois river prior to the opening of the Drainage canal is that the sewage from the Illinois and Michigan canal does not disappear by the time it gets to Grafton. I never took any samples of Illinois river water at Peoria before the opening of the Drainage canal.

1668 The reason I am able to express an opinion on the matter is because there are data of responsible investigators at hand showing the chemical character of the Illinois river at Peoria that enable conclusions.

Q. Why is it that the sewage from Chicago prior to the opening of the Drainage canal would purify itself in running 350 odd miles when the sewage from Peoria does in going less than 150 miles?

A. First of all, I don't concede that the sewage from Peoria purifies itself from a general hygienic standpoint during that distance. I only assert that the effects of the pollution of the Illinois river from the sewage of Peoria are not discernable in the chemical analyses as far as chemistry is concerned, from the samples collected at Grafton several miles above the mouth of the Illinois—as far as chemistry is concerned.

Q. If that is true, doctor, what you have just stated, can you determine whether the sewage which you found at Grafton is Chicago sewage or sewage from Peoria?

A. It can only be ascertained what the effect of discharge of Peoria sewage into the Illinois river is on the sanitary character of the Illinois river, that is the only thing that can be ascertained.

The conclusion is justified that since the chemical analysis of samples of water taken at a point a few miles above
1669 Peoria, the chemical character shows certain conditions of the Illinois river at that point, that after the introduction of the Peoria sewage into the Illinois river, before the Illinois river reaches Grafton, the chemical character of the water at Grafton is of a certain character, comparing that character with the character found in the water above Peoria, the conclusion is justified that the effect of the Peoria sewage on the Illinois river has disappeared, and the general pollution of the Illinois river as established above Peoria continues in a measure to the mouth.

Q. Can you determine by your analysis at Grafton, if what you stated before is true—Chicago as distinct from Peoria sewage?

A. That could not be done. Nobody could do that.

Q. That includes yourself, does it?

A. Yes, sir. Hypothetically I would say that since the Illinois river showed such high pollution during its route from La Salle to Peoria, and this high pollution being found throughout all our investigations, that while the absence of sewage from Peoria might reduce that figure, it is my opinion now—hypothetically—that the pollution of the Illinois river, without the addition of the pollution from Peoria, would prevail to a sufficient extent to still render that water as found a few miles above the mouth of the Illinois, unpotable.

Q. Would it be to such an extent to the same degree under those conditions as it would if supplemented by the sewage of Peoria?

A. Well, I have already answered that question; that I said that while there might be less of pollution noticeable at the mouth of the Illinois river in the absence of pollution from Peoria, that still the pollution of the upper Illinois, before it reaches Peoria being uniformly high, as found throughout all our investigations, this pollution would still prevail to a certain extent at the mouth of the Illinois, rendering the water of the Illinois river at its mouth unpotable. As I have

1671 already testified, if the Illinois river water before it reached Peoria would be pure chemically the effect of the pollution of Peoria sewage in the Illinois river would not be discernible at Grafton. From the examinations and the sources of information I had at hand I concluded that the Illinois river was a polluted stream prior to the opening of the drainage canal. I atrtibuted that pollution to sewage pollution from the Illinois and Michigan canal. I did not investigate whether the tributaries of the Illinois contribute any pollution for 1899. I had no data to that effect.

1672 As I have testified before, when the stages of the tributaries are low, the pollution from these tributaries is inappreciable. When they are high, it may be possible that at times—when they are very high, and they sweep out considerable pollution that has accumulated in the course of the tributaries—that that pollution may have some influence in increasing the pollution found at Grafton. I do not know, off-hand, whether the sewage unconverted that emptied into the Des Plaines river from the Illinois and Michigan canal exceeded in volume and quantity all the other sewage from the tributaries and from the cities along the banks of the Illinois river between Lockport and Grafton.

1673 I think that the sewage coming from the Illinois and Michigan canal would be larger than from the tributaries and from those small cities along the route.

1680 The addition of water does not increase or decrease the quantity of polluting substance in that water.

1682 At times of low stage of the Ilinois river the sewage that entered the Des Plaines river from Chicago prior to the opening of the Illinois and Michigan canal was greater than the sewage from all of the tributaries of the Illinois river and the cities that were built upon its banks from Lockport to Grafton. I could not state how much greater, because I would have to consult the original data.

1683 I have made such calculations several years ago in preparing my report on the investigations in question here. I do not recollect how much sewage I gave to Peoria. The sewage from the city of Chicago at that time I figured hypothetically from publications by authorities who had expressed opinions on the quantity of sewage from Chicago.

Q. I asked you if any sewage from Chicago entered the Illinois and Michigan canal except at the pumping works at Bridgeport?

A. To my knowledge at this moment, only at Bridgeport.

1684 It is a fact that not a drop of the sewage from the Chicago river enters the Illinois and Michigan canal except what is pumped in there. At times of low river stages I say that exceeds the sewage polluted water that comes from all the cities lying on the tributaries of the Ilinois river which empty into the Illinois river.

1685 I have not made an estimate of the cause of the effect of the sewage of Springfield, Illinois, on the Sangamon river. It wasn't necessary. I based my estimate as to the amount of sewage draining into the Illinois river from Joliet, on the water supply of the city of Joliet. My estimate of Pekin I made upon chemical analyses of samples of the water taken above and below Pekin. The quantity of sewage from Peoria I based upon the water supply; that was to include all
1686 the sewage from the city of Peoria. I do not know directly how many tons of sewage or refuse is drained into the Illinois river every day by the distilleries of
1687 Peoria. Prior to the opening of the drainage canal the Illinois river was a polluted stream. In 1899 there was

somewhat of an epidemic of typhoid fever in St. Louis. There were 482 cases reported in November, 1899.

1688 The only other month of any year in which the number of typhoid fever cases exceeded that of November, 1899, was in 1892. I have not got the data at hand now, but it is my impression that it was October or November, 1892.

1689 No reason has been found for explaining the presence of typhoid in 1899 in St. Louis, to my knowledge. That was before the opening of the drainage canal. Since the opening of the drainage canal we have not had as many as 482 cases of typhoid in St. Louis in any one month.

Q. Then the conditions in the public health of the city of St. Louis since the opening of the drainage canal has never reached the point in typhoid that occurred for any one month in 1899. Is that correct?

A. If based upon the estimate of one month you are right. The data I get my information from, that the Kaw river runs through a salt country is "Mineral resources of the United States. Calendar year 1887. United States Geological Survey." A tabular presentation of salt deposits in the United States, published in this government publication, page 732, in the column, "Mineralogical Name."

1690 Several tributaries of the Kaw river, as well as the Kaw river itself—the Kaw river being 300 miles long—drain through several of these counties which are mentioned here as having salt deposits. I have no other sources of information on that subject from literature.

1691 (Wtiness states what potable water consists of.)

1693 (What is potable water, or not, depends upon public health statistics.) If the public health statistics show that the water does not have any injurious effect upon the public health, such water can be considered permissible.

1694 DR. WILLIAM C. TEICHMANN, re-direct examination by Mr. Jeffries: Information I have, aside from literature and geological reports, that leads me to believe that the Kaw river runs through salt laden territory consists of the results of chemical analyses made of samples of water collected from the Kaw river. Assuming that the waters of the Illinois river have been condemned as unpotable; that the immediate tributaries of the river have likewise been condemned as unpotable and assuming the fact that the effect of the waters of the Illinois river on the Mississippi at their junction, or at any point below their junction did not render the Mississippi unpotable prior

1695 to the opening of the canal, the effect of the opening of the canal carrying the Chicago sewage into the Illinois river, upon the Mississippi river water, from my chemical analyses, was a polluting effect and rendered it unpotable.

RE-CROSS EXAMINATION by Mr. Todd:

If water is unpotable the addition of additional sewage will render it more unpotable. The increased pollution caused by the entrance of the Drainage canal into the Illinois river would, of course, have an increased effect on the public health of such community as would use that water for a water supply.

1696 Q. If the people thought that they wanted to use that water and did use it, it would be potable for all practical purposes, would it not?

A. You mean after the increased pollution? Yes, sir.

RE-DIRECT EXAMINATION by Mr. Woerner:

I meant, in answer to the last question asked by Mr. Todd that the potability of the water could only be judged by its effect on the public health. I determine the potability by chemical analyses and a general consideration of the analyses from a chemical and bacteriological standpoint. That is a theoretical way. The practical way would be to judge its effect on the public health.

Q. Has the people's judgment anything to do with the potability of water?

A. Well, the experience of the people in drinking the water may enable them to form an opinion.

1697 A chemist without knowledge of local conditions from analyses can not pass upon the potability of water in streams.

PROF. EDWARD H. KEISER, resumed the stand for further direct-examination by Mr. Jeffries:

1698 I have made an examination from data furnished me by the Board of Health of St. Louis of the condition of the water supply of St. Louis subsequent and prior to the opening of the Drainage canal. In the first place I tabulated all the analyses that were made of the waters of St. Louis prior to the opening of the Drainage canal and I find that the records go back to the year 1894.

1699 (Gives results of analyses made prior to the opening of canal.) Comparing these averages obtained in different years, we see that there are but very slight changes in the character of the water supply at St. Louis. The free ammonia ranged between .019 and .063 parts per million. The nitrites varied from .002 to .005; the albuminoid ammonia from .310 to 1.033, and the nitrates were practically constant. The maximum value for free ammonia before the water of the Drainage canal reached St. Louis was .138 on January 21, 1900, and for nitrites the maximum value was .01 on the same day. These analyses that are recorded prior to the opening of the canal show that the water was comparatively stable, and that it was not an unwholesome water compared with its present condition.

1700 (Witness gives results after opening of canal.)

1701 A portion of this great increase in free ammonia and nitrites noticed in February and March, 1900, may have been due to the fact that in the winter months, impurities are usually found to run higher than in spring and summer. (Witness reads table showing results for free ammonia, nitrites, albuminoid ammonia, nitrates and chlorine for various months in 1900 and 1901.)

1702 Comparing the average results for this table with the average results before the opening of the canal, we see that there has been a very decided increase in each of these forms of nitrogen and that the chemical analyses show a permanent pollution of the water.

MR. JOHNS: I move to exclude the entire answer of the witness to the last interrogatory as argumentative.

In looking over the statistics of the Health Department of the city of St. Louis I found 11 analyses of water of the Missouri river at a point above the mouth of the stream, are on record.

MR. JOHNS: I object to the announcing of results of those analyses and the average of them, on the ground that it is all of record, as testified to by the witness.

1703 Witness gives table of average results of analyses of Missouri river water made by city chemist until October 10, 1900, and also during period October 1, 1901 to November 30, 1901.

MR. JOHNS: Same objection.

Comparing these averages now, with the averages of analyses before February 1, 1900, we see that there is but a
1704 slight difference in the average condition of the Missouri river during these two periods. In other words, the Missouri river during the period of September 2, 1899 to November, 1901, has undergone no permanent change in its sanitary character. We see from these that while St. Louis water had undergone a marked deterioration, the Missouri river water had remained unchanged. (A reference to these tables will show that the Missouri river did change, and that there was not much of a change in the Mississippi water at the intake.) It is true that in the winter months the impurities in this river (the Missouri) are higher than in the summer. This is true of all streams, but we see that in the fall of 1901 the water had again returned to its former condition. These results show then, that the increase of impurities in the St. Louis water did not come from the Missouri river.

MR. JOHNS: I move to strike out the entire answer as an argument.

1705 Witness reads average of analyses made of Mississippi river water by health department, of 17 samples collected at Hartford, one mile above mouth of Missouri river. Samples were collected between August 3, 1899 and December 4, 1899. Also averages for same point from daily analyses of samples taken from January 23, 1900 to October 10, 1900, and from October 1 to November 30, 1901. (Witness averages both series after the opening of the canal. A reference to the results on pag 1705 will show that the average for 1901, after the canal had been opened a year, are much lower than right after opening of canal.)

Comparing these results with the average condition of the Mississippi river at the same point before the opening of the canal we see that there has been a permanent increase of the pollution of the water.

1706 The water of the Mississippi, like that of the St. Louis intake, has been very materially inferior in sanitary quality since February, 1900, and further, these analyses show that since the St. Louis water is a mixture of the water of the Missouri and Mississippi, the increased impurities of the St. Louis water must have come from the Mississippi river and not from the Missouri river.

MR. JOHNS: I move to strike out the latter part of the answer as an argument.

Between September 6, 1899 and January 17, 1900, 18 samples were collected from the Mississippi river at a point above the mouth of the Illinois river. Daily analyses were made from January 23, 1900 to October 10, 1900, and from October 1, 1901 to November 30, 1901. (Witness gives results of these examinations.)

Comparing these with the results as given, we see that
1707 the Mississippi river above the mouth of the Illinois, while higher in impurities in the winter months, returned in the fall of 1901 to a condition very similar to that which it was in 1899. Plainly, then, the upper Mississippi river is not the source of the impurities that pollute St. Louis water.

19 samples of water of the Illinois river from a point 3 miles above Grafton we re-collected and analyzed by the city chemist at intervals between September 6, 1899 and January 17, 1900. (Witness gives average values.)

THESE RESULTS SHOW THAT AT THIS TIME THE WATER WAS BADLY POLLUTED AND NOT FIT FOR DRINKING ACCORDING TO ACCEPTED STANDARDS. (This was before opening of canal.) From January 23 to October 10, 1900, averages were as follows (see 1707). For October and November, 1901, the averages were as follows (see 1707.)

1708 (Witness then takes averages for both series taken after opening of canal and compares with one series taken before opening.) We see from these that for the ten months since the opening of the Drainage canal there was an increase in free ammonia of nearly 27 per cent and of nitrites 167 per cent. We can only conclude from these figures that after the canal was opened there was a much larger quantity of sewage undergoing putrefactive changes than before 1901. The analyses have shown that both the Missouri river and the Mississippi river above the Illinois have undergone no permanent change but the Illinois river has been rendered more impure as a result of the opening of the Drainage canal. (A proper comparison would be the results obtained prior to opening of canal with the period of October and November, 1901. During the year 1900 the accumulation of sewage was being carried through the canal—this sewage having accumulated before the canal was opened. Such a comparison would be as follows:

From September 6, 1899 to January 17, 1900: Free ammonia, .215; nitrites, .012; albuminoid ammonia, .553; nitrates, .8; chlorine, 25.0.

For October and November, 1901: Free ammonia, .110; nitrites, .043; albuminoid ammonia, .373; nitrates, 1.71; chlorine, 21.0.

This comparison shows less free ammonia, more nitrites, less albuminoid ammonia, more nitrates and less chlorines in the samples prior to opening of canal than after opening of same. Increased nitrates means an advanced state of purification. Therefore the water is much better after the opening of the canal than it was before with the exception of higher nitrites.)

There were no analyses of the water of the Illinois river at points above Grafton made by the city chemist before the opening of the canal. But from January 23, 1900 to October 10 of the same year, daily samples were taken at a point three miles above Peoria and occasional samples at Joliet and at Lockport. These
analyses show that as we ascend the river from Grafton
1709 to Chicago, the water becomes steadily more and more
impure. (See average results of analyses at Grafton, Peoria, Joliet, I. & M. canal, Drainage canal, Lockport, Bear Trap dam and Lake Michigan.

1710 Q. Now, what conclusions do thes results show, or lead you to?

MR. JOHNS: I object to the question, as the conclusions have already been testified to and are not, at any rate, competent evidence.

A. We see that the entire Illinois river is in a highly polluted condition. Going down to Grafton, we find that the free ammonia has fallen, but still is far from being in a condition fit for drinking. We see that the oxidation and self-purification processes become very slow as the concentration of the sewage is diminished, and for the same reason we find these impurities in the water of the Mississippi and the water of the St. Louis water works.

MR. JOHNS: I move to exclude the answer as an argument.

(Comparisons shold be made of the average results shown as testified to by this witness from page 1697 to page 1710.)

CROSS-EXAMINATION by Mr. Johns:

1711 As to these samples taken in 1903 and 1904, I have no
knowledge as to how they were taken or analyzed except as stated in the report of the Water Commissioner of St. Louis for 1894, page 418. The samples of water referred to in Ap-

pendix I, annual report of the Water Commissioner for year
ending 1894 were taken at St. Louis intake, but I don't know
what time elapsed after the taking until they were analyzed.
I do not regard the St. Louis intake the same thing as the dis-
tributing well, but the water is very much the same. The
samples upon this paper (appendix) which I enclose in pencil
mark, are from the distributing well and from the clear
1712 wells. As to any of these samples in the paper described
in Group D and Group C, I cannot tell at what time they
were taken either from the distributing well or from the clear
wells, or how long a time elapsed until they were analyzed after
they were taken. I do not know anything personally in refer-
ence to the manner in which those samples were kept or the plan
by whcih they were analyzed, except what I have read in that
report. In reading of these results I do not state the amount
of oxygen consumed, simply to make the report concise and
not to overburden the report with the table of figures. There
was a statement of total solids as to those samples of May 2,
1893, to January 24, 1894, in group D, and from April 14, 1893,
to January 24, 1894, in group C. I did not state the solids,
simply because it would throw very little light on the sanitary
condition of the water. I regard the question of solids
1713 in solution as having very little to do with the potability
of the water. There were no statements in the report of
chlorines. I would be able to give an opinion as to the sanitary
condition of the water without a knowledge of the chlorine.
In order to determine the potability of water there should be
taken into consideration the chlorines; the oxygen consumed
is not always taken into consideration; it assists in form-
1715 ing an opinion. I have no personal knowledge of the
samples taken in 1892 to 1904, nor of those taken from
September 9, 1899, to January 22, 1900. I have taken the figures
from the tables furnished by the city chemist. I do not
1719 know anything personally as to the eleven analysis of
water taken from the Missouri river above its mouth from
September 2, 1899, to December 4, 1899. I did not give the

oxygen consumed nor the chlorines because it would have
lengthened this statement very much. The chlorine is not of
any importance in the Misouri river, because the Mis-
1720 souri river is highly charged with chlorides which is of
mineral origin. I have no knowledge of that, only in so far as
the analyses show this water comes from the Kaw river. I
have no personal knowledge as to the Kaw river. The results
as to that water enable me to form an opinion that it is a fair
drinking water—not above suspicion, but still it is drinka-
ble. I come to that conclusion without reference to the solids
in solution or suspension or chlorine or oxygen con-
1721 sumed.

Q. Referring to the sanitary condition of the Mississippi river between August 3, 1899, and December 4, 1899, having free ammonia, .107; nitrites, .004; albuminoid ammonia,, .622; nitrates, .5, is that water potable?

A. I should say that was unsanitary water and water that had reached the limit. It shows so much impurity in that water that it ought not to be used for drinking purposes.

Q. Would you consider water having the following parts, namely: Free ammonia, .107; nitrites, .004; albuminoid ammonia, 622, and nitrates, .5, a potable water? A. No, sir.

Q. Now, that was the average condition of the Mississippi river as given in your tables, before the opening of the canal?

A. Yes, at a point above where it mixes with the Mis-
souri. As a chemist and without reference to this ques-
1722 tion, if I had been called upon to analyze a sample of
Missouri river water, not knowing that it was Missouri
river water, considering the high chlorine in that sample, I
would have been inclined to condemn that water as unpotable.

RE-DIRECT EXAMINATION by Mr. Jeffries:

1725 These (indicating paper) are the printed analyses of
the water taken from the distributing well and the
settling basin of the St. Louis waterworks in 1893.
1726 This paper is from the annual report of the Water Com-

missioner for the year ending April, 1894. The system used in making this examination is stated on the next page in the report. I have read the methods described in this report, and they are the usual standard methods used in analyzing water.

(Page offered as complainant's Exhibit 36.)

MR. JOHNS: I object to the paper with the proposed addition, as it is not a public record and not such a publication in any event as becomes competent evidence.

The first one of these two papers (indicating) give the result of twenty-one analyses of samples of St. Louis water, made from December 15, 1892, to April 20, 1894, in the chemical laboratory of Washington University. That was tap water. (Offered in evidence as complainant's exhibit 37.)

MR. JOHNS: Same objection as made to exhibit 36.

1728 This sheet contains results of daily analyses of water from the Missouri river at Fort Bellefontaine from January 23, 1900, to February 1, 1900. They were made under my direction in the chemical library of Washington University. (Offered in evidence as complainant's Exhibit 38.) 1729

MR. JOHNS: Same objection as made to Exhibit 36. These twenty-eight sheets of paper (indicating) contained the records of analyses made by the city chemist of St. Louis of samples of water taken in the Misouri river at a point above its mouth in 1899, 1900 and 1901, and at the intake tower, Mississippi river, at Hartford, Mississippi river at a point above Grafton; Illinois river at a point above Grafton, all the above for the years 1899, 1900 and 1901, and for the Illinois river at a point three miles above Peoria, at Lockport and Joliet, in the years 1900 and 1901, and of the water of the drainage canal in 1900, and of the Illinois and Michigan canal in 1900, and of Lake Michigan in 1901. Some are the daily analyses and the weeklies have been added on the bottom, and some are the 1730 weekly averages. Mr. Miller and Mr. Getz, together with the city chemist, prepared them. (Offered in evidence as com-

plainant's Exhibit 39.) The evidence which I gave this morning was based on complainant's exhibits from 36 to 39, inclusive. The averages to which I testified this morning were cal-
culated from the data contained in those tables. The
1731 water analyzed within the days mentioned in Exhibit 37
came from a place known as Bissell's Point, before the
1732 removal of the intake to the present location at the Chain
of Rocks. I think this water which was analyzed had passed through the settling basins. I am not certain, because I was not a resident of St. Louis at that time. As to the derivation or character of the samples of water out of which the results in Exhibit 37 are tabulated, I know nothing.

J. L. VAN ORNUM, examination by Mr. Jeffries:

1733 Live in St. Louis; am professor of civil engineering at
Washington University at present. Graduated in 1888
at University of Wisconsin. In March, 1903, I made in-
1734 vestigations to determine the time it will take for water
to flow from Chicago through the drainage canal, the Des Plaines river and the Illinois river and the Mississippi to the water works intake at St. Louis. Investigation was intended to be divided into three sections, one from Chicago to Peoria, another from Peoria to Grafton, and a short and third section from Grafton to the water works intake. The character of the weather and the conditions of the rivers concerning driftwood made it impossible to follow the floats except during the daytime. The floats were taken out of the water during the night, and their progress was followed and watched from the point where they were taken out the day before continuously during the day until they were taken out again.

1735 The floats used were what is technically known as submerged floats—that is to say, a lower portion consisting of curved vanes so that in whatever position the vanes turned there shall be a considerable area exposed to the force of the current. This is connected by as light a chain as is practicable, to a portion floating on the surface of the water, which offers buoyancy enough to cause the whole affair to float.

1736 The submerge dportion below the surface was one foot, two feet and three feet and those used on the Mississippi this distance were regulated to be about two, four and six feet respectively. The work was first begun on Saturday, March 14, 1903.

1737 I had personal knowledge as to the results I am about to testify to—as to a part of them. I followed some of these floats myself. Others were reported to me by the parties who did follow them.

MR. TODD: Now I want to interpose an objection to the testimony of this witness in regard to all the other floats that were followed by other parties than the witness himself as being incompetent. I learned from the field notes submitted to me and verbal reports given by the observers that on March 15, the party starting in the Drainage canal placed the floats in that canal at Western street bridge following them on that day to the C. & C. T. bridge during a time of 7 hours and 59 minutes. The floats were left in the water during the night and it was the intention to overtake them in the morning but before they were overtaken it was found that these floats had been removed from the canal. It was, therefore, necessary to resume the observations over that same distance of the canal which had been covered by the floats during the night.

1738 The time consumed was a total of 33 hours and 46 minutes from Western street bridge to the Bear Trap dam at Lockport. These floats were not started at Robey street. This omitted distance is about 2,800 feet and we should add about 40 minutes to the total time above given, which would probably make the time from the south branch of the Chicago river to the Bear Trap dam as about 34 hours and 26 minutes. The gauge at the Bear Trap dam when this point was reached read minus 2.3 feet, and the depth of water flowing over the dam was 4.4 feet. This is said to correspond to the discharge of 295,000 cubic feet per minute, or about a normal flow.

1739 The time from the Bear Trap dam from Joliet was observed to be 2 hours and 15 minutes. On the 17th, the observations were carried from Joliet to a point marked by a flag on the bank, two miles above a certain place where they stopped over night. The time here was 3 hours and 36 minutes. On March 18, the floats were followed from this same point to another marked point, one mile above the DuPage river, the time being 3 hours and 6 minutes. At about this point practically all the floats which were made and which were of the character I have described, were lost. To provide against the necessity of giving up the observations entirely, temporary floats were devised which were used in connection with those remaining floats of the character with which they were provided, and were run continuously and alongside of them. Fortunately these submerged floats remaining were not lost and it was only from Chillicothe to Peoria that the temporarily devised floats were used entirely. On the 19th the floats were observed from this point one mile below the DuPage river to Morris, during the time of 7 hours and 54 minutes. On the 20th, the time from Morris to Seneca was 5 hours and 2 minutes, and from Seneca to Marseilles, without any interruption at Seneca, 2 hours and 15 minutes. On the 21st, the floats were observed from Marseilles to Utica, the time from Marseilles to Ottawa being 2 hours and 7 minutes. From Ottawa to Utica 3 hours and 36 minutes.

1740 On the 22d, from Utica to a point at Depue, the time from Utica to LaSalle being 2 hours and 28 minutes; from La Salle to Peru 58 minutes; from Peru to Marquette 5 hours and 6 minutes; from Marquette to the point at Depue 1 hour and 1 minute. A total from the Bear Trap dam at Lockport to Peoria of 102 hours and 26 minutes. From Peoria to Pekin, 4 hours and 30 minutes. For clearness, I will say that my personal observation of the floats of this party was only the starting of them.

1741 From Pekin to Kingston, 3 hours and 17 minutes, the total time from Peoria to Grafton, 102 hours and 27 minutes.

1742 I, in person, observed floats in the Mississippi river from the point at Grafton where the observations were discontinued as described, through the Mississippi river to a point opposite the St. Louis waterworks intake. The time from Grafton to Alton was 6 hours and 36 minutes and from Alton to the intake tower, at the Chain of Rocks, 4 hours and 34 minutes. The total time from Grafton to the waterworks intake was 11 hours and 10 minutes. This makes a total time as observed from Lockport opposite the Bear Trap dam to opposite the waterworks intake, at the Chain of Rocks, St. Louis, of 9 full days and 3 minutes and as I have said before, including the 40 minutes calculation, about 34 hours and 26 minutes through the Drainage canal, or a time noticeably less than ten and a half days from the south branch of the Chicago river to opposite the waterworks intake at the Chain of Rocks. These floats of the submerged character that I have described are those ordinarily used by civil engineers to determine the velocity at a certain depth.

1744 The Mississippi was at about half stage, that is the gauge readings at that time indicated the heighth of the river about one-half its extreme flood stage. The reading at Grafton on the morning of the day when these observations were taken, was 16 feet. The reading of the St. Louis gauge on that day was 24.3 feet. The wind on that day was in general up stream, never having a component down stream; sometimes the wind coming partially from one side and sometimes from another—the windings of the stream making the wind vary from one side to the other.

1745 The velocity of the wind varied probably from about 5 to 12 miles an hour. The floats were placed in the lower end of the Illinois in such a way that they spread across the river, one in the center, one about half way from this one to the right bank and one about half way from the center one to the left bank.

1746 That was in the mouth of the Illinois river. As they flowed into the Mississippi they moved closer and closer to the Illinois shore of the Mississippi and in a general way, from the Illinois river to below the mouth of the Missouri, they were more or less close to the Illinois shore, sometimes in the extreme going to the middle of the Mississippi, but most of the time being within three or four hundred feet of the Illinois shore. At about two miles above the waterworks intake, for instance, the floats were quite close to the Illinois shore, probably about 50 feet from it, but from this point on down to the waterworks intake, the floats rapidly left the Illinois reaching the middle of the Mississippi and finally passing the waterworks intake, between the intake and the Missouri shore—all of them and somewhat closer to the Missouri shore than to the intake. The distance from the Missouri shore to the waterworks intake is about 1,500 feet and from that I judged that the floats passed the intake about 700 feet from the Missouri shore.

CROSS-EXAMINATION by Mr. Johns:

The stage of water in the Des Plaines river is very fluctu-
1747 ating. The guages were read by these engineers as they
passed them wherever they saw them, but beyond that I know nothing about it. I have been unable to get such readings. I have no exact knowledge of the stage of the Des Plaines river as to the time that these floats were in the river. The river was high. At the time the floats were placed in it the Illinois river was high—it was very high. The bottom lands and the overflowed land along the Illinois river was very ex-
1748 tensive.

It may be that the river was sometimes four or five miles wide, in very high water, from waterline to waterline. The ordinary banks of the river at all places were overflowed, the water extending out into the bottoms. In the Des Plaines river five floats were put in at one time. They were put in at the same places and at the same time. We had floating down the Des Plaines river, under observation at the same time, five different floats—that is, through a portion of it, but from time to time the floats were lost, so that before reaching the mouth of the Des Plaines river I believe that one or two more had been lost. The plan was to distribute them across the channel por-

tion of the river. By channel I mean that part which is the swiftest moving water, as near as could be judged. I had in the Des Plaines river floats of different lengths, one to three feet. I continued that also in the Illinois river. As a
1749 rule the longer floats were placed in deeper water, in the center of the channel. When these floats were placed in the water on a cross-section of the river I understand that the tendency was towards separation, although there was nothing very marked to be observed in that direction. The stage of river throughout our observations in the Des Plaines and Illinois being in a condition of overflow caused them to rather seek the banks. Quite often it was found that they were aground; then they were released and taken back.

Q. Did those floats in the Des Plaines river keep abreast of each other if they were floating rapidly?

A. That would depend largely upon the wind, sir, whether they would keep abreast of each other or not. In general they would keep abreast of each other.

1750 As to which one would advance more rapidly, that would depend whether the wind was more up stream or more down stream. In general the wind was more than otherwise up stream, or had a component up stream, which would affect the shorter float more and hold it back. I could not say whether the direction of the wind would have a considerable effect upon the direction in which the floats went down the river. The effect would be small compared with the effect of the current, of course, but it would have a certain effect. Of course it was generally noticed that during a half day's or a day's run that the floats would work toward the leeward side of the
1752 river.

It is a fact, as a general observation, that the float nearest the center of the channel traveled most rapidly. The floats nearer the shore were much slower.

1753 Whenever I have mentioned a time here that the float was taken out it was the time of the arrival of the most advanced float at that point. The total time of nine days and three minutes is the fastest time that these floats made down the Illinois river. I have no knowledge of how rapidly the current flowed at the side or the banks of the Ilinois river, except for one portion between Peoria and Pekin, when I simply observed a very slow current at the side of the banks of the stream. I haven't any doubt it was less than a foot a second and very much less.

Q. So that all your observations have determined is the quickest time of the most swiftly flowing water from Lockport to Grafton?

A. Under conditions existing at the time the observations were made, yes, sir.

Q. Isn't it true that the current of the Illinois river at the time of these observations was very much swifter in its channel than at the ordinary stage of the river?

A. I suppose it is.

Q. Is it not true that it was very much swifter than at the low stage of the river?

A. Undoubtedly.

1754 The Mississippi was at about half its flood stage.

1755 The lowest water known at St. Louis was 2.5 feet below the zero of the St. Louis guage. In a straight piece of river the center of the channel is that part of the river in which the flow is swiftest. If it is curved it is swifter toward the concave bank and sometimes very close to the concave bank.

In general the water on the surface flows slower than that
1756 two feet below.

The longest chain I used on a float in the Illinois river was three feet and the shortest was one foot.

1757 In the mississippi river these floats hugged the Illinois shore below the entrance of the Missouri river to two miles above the waterworks intake, then above the intake they started across the river. Ther were only two then. We started with three, but the chain parted and one was lost below Alton. I think from Alton down there were only two. About two miles above the intake both floats were about fifty feet from the Illinois shore. One of the chains to these floats was six feet long and the other four feet.

1758 I am wrong in what I just said. The floats were about fifty feet from the Illinois shore at a point where the Missouri river enters the Mississippi. A mile below this point both floats were three or four hundred feet from the Illinois shore. Two miles below this point the red, No. 5, which is the six-foot float, was 200 feet from the Illinois shore and the four-foot float was 400 feet or thereabouts from the Illinois shore. In passing the upper end of Chouteau's slough, still nearer the water works intake, the four-foot float was 600 feet or thereabouts from the Ilinois shore, and the six-foot float was about 100 feet in the rear and about 100 feet from the Illinois shore, and just below that the six-foot float kept moving still further toward the left, and was about to pass at what is called by river men the chutes —that is a passage to the eastward of the island opposite the intake, and was pulled out of the water and put in again opposite the four-foot float, which had not been disturbed, and about sixty feet to the left of it. That is, sixty feet toward the Illinois shore from the four-foot float. That is below the Madison Point light; and still the six-foot float kept working off toward the left and moving toward those chutes, as they are called, behind the islands, to the east of them, and was pulled out again and put in abreast of the four-foot float about sixty feet toward the Missouri shore—at this time, from it. From that time on they both kept on very closely together, the six-foot float, however, lagging behind, but with reference to the shore they seemed to keep or work toward each other, and crossed opposite the intake at about the same distance from the shore. That is to say, the red was disturbed twice; the six-foot float was disturbed twice between Alton and the water works intake. The four-foot float was not touched.

1759 When I say that the floats were close to the shore at a point where the Missouri river enters the Mississippi I mean that the floats passed the mouth of the Missouri river at Missouri River Point, as it is called on the river, at about fifty feet from the Illinois shore of the Mississippi river—that is, the left bank of the Mississippi.

1760 The Mississippi at that time was at about a half stage, and so was the Missouri. At the lowest guage I could get on the Missouri on this date the reading was 15 and one-half. This is at Hermann. The high water is 35.6, indicating very much the same thing as the stage of the Mississippi. The Missouri river where it enters the Mississippi was very wide at this stage. The floats kept along very steadily. They were aparently so close to the Ilinois shore that they were not affected at all directly by the inflow of the Missouri river.

1761 I don't know of any dikes in the river along the Ilinois shore oposite the mouth of the Missouri river and below that down toward St. Louis. If there were such dikes they would, to an extent, affect the direction or velocity of the current for such a stage as I have described. The floats passed the intake itself on the west side and between that and the shore.

1762 I took them out immediately below as soon as I could get them after timing them as they passed. Both the floats went over there, one of them, as I have stated, however, being removed and put in again, which destroys any significance that may be attached to it.

I should think it is 5 or 6 miles from the mouth of the Missouri to the Chain of Rocks.

1763 In another mile or two the four foot float was somewhat farther from the Illinois shore—perhaps 600 feet and the six foot float was still closer to the Illinois shore, or about 100 feet from it perhaps. This was at Chouteau's slough, that is about three miles below the mouth of the Missouri river. The Mississippi at that point between its normal banks I think is about three-fourths of a mile wide.

1764 It is practically four miles from Chouteau's slough to the intake, by the course followed by the float. Now below the point where the six foot float was about to go into Chouteau's slough, there is a sand-bar or island. In low or medium stage it is quite a large island and the general current of the river goes around to the left of the island, as you go down the river. It certainly must be the general current of the river at low water when there is practically no flow here and the course of these floats indicated it to be the case at medium stage.

1765 If the red float had not been interrupted, it would have gone through Chouteau's chute, as the river men call it. I was afraid of it. If it had done so, it might have gone below and to the left as you go down the river, of three other islands or two other islands, between that and the Chain of Rocks. That float might have gone to the left of three islands between Chouteau's slough and the intake, if it had not been interrupted at that time. There was a decided current that way and in order to prevent it going that way, I took it out of the water and placed it in the same channel of the Mississippi.

1766 The general direction of the Mississippi river from Chouteau's slough to the Chain of Rocks is very crooked in that vicinity. Its flow at Chouteau's slough, as I recollect it, is about southwest and from that direction there is a gradual curve until at the Chain of Rocks I believe the Mississippi river flows nearly south.

CROSS EXAMINATION by Mr. Todd:

1767 I did not make any investigation as to the volume of water coming down the Illinois river at the time this ex-
1768 periment was made. At the time these experiments were made, the river was much higher than the average condition of the river. In fact, it was overflowing the low lands. The necessary accompaniment of that fact is that the current was swifter.

1769 Q. If the water was six to ten feet above the crest of the dams at Henry, Copperas Creek, LaGrange and Campsville, at the time you made the experiment that would indicate that there were flood waters in the Illinois river.

A. It is a fact that at the time the experiment was made
there was a great amount of flood water in the Illinois
1770 river. My experiments were based upon conditions when
the river had fallen. It had passed its crest, the highest
water had occurred shortly before the observations were taken.
So as a general principle I can say that the length of time occupied and recorded here is probably greater than it would have
been if the observations could have been made when the river
was at the same stage but still rising. I do not know what
1771 the proportion of water in the channel was to the water
in the Illinois river outside of the channel. As far as I
1772 saw the water in the basins beyond the banks of the river,
or rather the water in the basins of the overflowed lands
had a barely perceptible current. As far as I saw it it was
practically in a stagnant slow condition.
1773 From my observations in this experiment I am not able
to tell what the velocity of the current would be if the
Illinois river was contained within its banks. The condition
that I found in the Illinois river does not obtain the year around.
I don't suppose it will obtain for a period of six weeks during
the year. I have no idea whether it would obtain for three
weeks. I presume the experiments I made would apply to the
Illinois river for a period not to exceed six weeks throughout the
year. The reading on the gauge at Peoria was 19.1 feet. The
way to interpret that reading would probably be by stating that
the low water reading for Peoria is 2.6 on the same gauge and
that the highest water previously on record is 21.9 feet.
1775 My experiment only serves to prove the velocity of the
current at a time and under the conditions that existed in the
Illinois river at the time that the experiment was made.
1776 The water of the Mississippi from Grafton to the intake
at the time of the experiment was what is known as high
1777 water. As to the sand-bar in the Mississippi heretofore
testified to, I understand that at low water stages, very
little, if any, Mississippi water passes to the left of the same.
There is a channel to the left of the sand-bar that were are talk-

ing about in the Mississippi river. The three islands south of the sand-bar were submerged when my observations were taken.

1778 After I left Joliet, some of the floats were lost again, mostly from floating into the woods from the side channels which are full at high water. That indicated that the waters of the river separated wherever there was an opportunity to do so and the current is more or less dissipated and the water went over and submerged the lands.

1779 RE-DIRECT EXAMINATION by Mr. Jeffries:

This chart is a tracing I had made to show the point at, or figures of time of the flow from really the Chicago river to the St. Louis waterworks intake, embodying graphically what was given in the figures this morning. It was prepared by me. The figures, for instance, were taken from tables furnished me by different United States engineering officers. (Said map marked complainant's Exhibit 40.)

1780 MR. TODD: I object to the map being introduced.

1782 RE-DIRECT EXAMINATION, by Mr. Jeffries:

That is a graphic representation of the gauge reading of the Mississippi river at Keokuk, Grafton and at St. Louis during the month of March, 1903, and at Hermann, Missouri, for the Missouri river for the same time. I prepared that from figures furnished to me by the weather bureau and in the case of Keokuk, by the figures furnished directly by the gauge reader.

1783 (Chart offered as complainant's Exhibit 41.)

This is a chart prepared by me showing the gauge readings in the Illinois river during the month of March, 1903, at Peoria, Beardstown and Grafton, Illinois. This was prepared by a table furnished by the weather bureau also. (Offered in evidence as complainant's Exhibit 42.)

MR. TODD: I object to both charts being offered as not competent and not prepared from any data which has been verified and known to be correct.

1784 The wind as it existed during these observations in its effect upon the float was not sufficient to drive it or carry it to the westward of the intake, supposing, of course, that without wind it would have gone to the eastward of the intake. I say it is very evidently the case in the first place, and it must be said that the wind does have an effect on the float, because it reaches the unexposed portion of the float, and the amount of that effect is a matter of computation, depending upon the circumstances existing. (Witness gives details of computation on which he bases his answer.)

1786 If there had been no wind, according to my conclusions, this four-foot float would probably have passed 450 feet to the westward of the intake instead of 800, as it did.

1787 Foat, white, No. 5, on which I wrote my name at the time it was used in the Mississippi river, is the one that passed, as I stated, about 800 feet west of the intake before it was taken out. (Offered in evidence as complainant's Exhibit 43.)

RE-CROSS-EXAMINATION by Mr. Todd:

At the time this experiment was made the water was wavy. I calculated the velocity of the wind simply from being obliged for a great many years to arrive at that from observation only. I did not have an instrument.

1790 The velocity of the wind that I give is an estimate.

RE-CROSS-EXAMINATION by Judge Springer:

1792 When I made these observations I was in a steam launch in the vicinity of the floats all the time. I got the measurements as to the relative distances from the shore of these lines by estimation, by eye and by experience in that class of work a great many years. I had no actual location or measurement. I made only one experiment between Alton and the intake as to the velocity of this float.

1793 The wind was blowing in a general direction from the southeast, that would make the waves move across the current of the river in a northwesterly direction. The force of the waves, whatever it might have been, would be to crowd the float northwesterly and therefore toward the Missouri shore.

C. V. MERSEREAU: I made observations of the
1794 velocity of the water in the Chicago drainage canal and
the Des Plaines river under the direction of Prof. Van Ornum. These observations were begun on Mach 15 and ended on March 26, 1903. For part of the work we used floats similar to the one exhibited here. Part of the time we used a float that was made of a white pine picket, about one and one-eighth of an inch square, on the bottom of which were nailed two pieces of tin, bent at right angles so as to resemble those floats.
1795 About 9 o'clock on March 16 the water guage of the Bear
Trap dam at Lockport was 4.4 feet.

CROSS-EXAMINATION by Judge Johns.

1805. The float was in the middle of the current a part of the time. I would put a float in the river and try to put it where I thought the point of maximum flow was. Whenever that float appeared to be working too much to one side I would go out and drop another float oposite to the first one and then let them both run from there and see which was running the fastest, and take up the one which was lagging behind, the object being to keep the float traveling as fast as I could discover current to make them travel. I was taking the fastest float, and if the float began to get slow I put in another one opposite and
1807 ran it.

In the drainage canal I read two guages, one at the Bear Trap dam and the other in the corner of the basin. I think the next guage I got was at Morris. The guage at Morris was 91.25, The next one I read was on the same day at the Seneca Railroad bridge. The guage was 95.0.

1809 I had the reading of the guage about a quarter of a mile above the dam at Marseilles. It was 98 feet even. At the Ottawa bridge the "10" figure was indistinct; it was either 80.6 or 90.6. At the La Salle bridge the reading was 81 feet. The guage on the Peru highway bridge was 14.75. At Henry the guage reader gave me the 1810 guage at 11.8 at seven in the morning. He gave me the high water of the Thursday or Friday before that at 13.4 feet.

1811 The actual time from Chillicothe to Peoria was 29 hours and 59 minutes. The progress of the floats, even in this high water, through Peoria lake, was very slow. No one float floated along uninterruptedly from Mossville to Peoria.

1813 CROSS-EXAMINATION by Judge Springer:

Q. I desire to learn the velocity of the float in Peoria lake, if you have a note of that, so as to indicte the velocity at that place?

A. I will have to work it out for you definitely; that is, the time here is not continual on account of putting in and taking out the floats. I would have to add the different times in order to give it to you. There was a very decided diffierence in the velocity of the floats in going through the narrows or through the lake.

CROSS-EXAMINATION by Mr. Todd:

1815 The floats were taken out of the water once on an average of every five minutes; that is, one float, that is where I was running five. As a rule the cause was that the float was not following the channel of the river. The country was overflowed and there was a tendency of the floats to leave the river and go out across the point, so that you had to be continually taking up a float that was on the inside and putting it on the other end of the line.

CROSS-EXAMINATION by Judge Springer.

1818 The total time of the float in going from the upper bridge at Peoria to the bridge at the central part of the town, which is approximately three miles, was 5 hours and 49 minutes, which would make one mile in about 1 hour and 56 minutes. It was practically one mile every two hours.

1819 The width of the lake oposite the city of Peoria was wider than when the river is at an ordinary stage. In other words, the river was out of its banks. All the way down from Joliet to Peoria the character of the water was a little turbid.

1820 I think that the water in the river was more turbid than
the water in the canal. I think the water that was coming in from the Fox river was rilier than the water in the Illinois—more turbid.

FRANK J. BROWN, examined by Mr. Jeffries:

1821 Employed by the waterworks of St. Louis. Worked on
the Illinois river last March to ascertain the velocity of
the current of the Illinois river. I started at Peoria and came
down as far as Naples.

1822 The total time was 71 hours and 40 minutes from Peoria
to Naples.

CROSS EXAMINATION by Judge Johns:

I started the floats about 50 feet apart, at Peoria, on
1823 March 14th. In going from Peoria to Pekin I had to take
them out of the water, some of them, because they
grounded, partly on the right bank of the river and partly on the
left. I think it was on the right bank the most, if I remember.
The river from Peoria to Pekin is quite tortuous. I think that
the one-foot submerged floats made a little the best time. The
three-foot was the slowest, except in case of high winds up
stream, and if anything they would fall behind, but in an ordinary current or wind, the red floats made the best time. If the
wind was high and blowing up stream, the three-foot floats
would travel the most rapidly.

1824 The gauge at Peoria, at the starting place was 19. At
the highway bridge at Pekin, on the 15th of March, it
was 13.6. At the State locks, the same day, 17.5—that is, the
Copperas Creek dam. At Havana, March 17th, at the highway
bridge, it was 16.9; on March 19th at Beardstown, it was 16.1.
At Meredosia, March 21, the gauge was 17 feet, nine and one-half; just below the boat landing at La Grange, 24.50, at the
upper end of the locks, and 24.25 at the lower end.

1825 CROSS EXAMINATION by Mr. Todd:

I said that with a very high wind blowing up stream the
free-foot submerged float made a little the best time. I think
at one time the wind was fully as high as 25 mile an hour.

1826 That is all a pure guess as I had nothing to measure it by.

1827 A ten-mile an hour breeze across stream would not affect the six-foot float at all. I noticed that the white float would make better time when the wind was blowing upstream. When the wind blew up stream the two floats did not go down the stream with uniform regularity.

1828 When the wind was blowing a gale, ten or fifteen miles an hour, I did not take the floats out of the water at any time. When they would get out of the channel or get too near the shore or get aground I would take them out. From Peoria down to Havana I had some trouble with them but it didn't seem to bother me so much after that. I do not know what was the cause of it, unless it would be the wind blowing from the bank driving them over that way. I noticed which way the wind was blowing, the floats always go that way. The floats would always go with the wind across the stream. The wind had a perceptible influence on the floats in going across.

1829 When the wind would come up at a ten-mile an hour gale it would some times be a couple of hours before they would strike the shore. I think that if they were out in the current, ordinarily they would go two or three hours without running ashore.

JOSEPH GIBSON, examined by Mr. Woerner:

1830 Am employed in the Water and Construction Departments. Made observations last March in order to ascertain the rapidity of the current of the Illinois river. I started from Naples, Illinois and went down to Grafton. I was 30 hours and 37 minutes from Naples to Grafton. Started from Naples on March 18th.

CROSS EXAMINATION by Judge Johns:

1832 At Naples the gauge reading equals 18 feet two and one-half inches. March 19, Chicago & Alton's draw-bridge, gauge reading 16 feet and 6 inches. Government gauge at Campsville, March 19th reading equals 24.7, that is above the dam. Saturday, March 21st, at Grafton the gauge reading was 17.0.

1833 Sometimes the floats would run into the drifts or drift out on the edge of the bank. When they did so, we would take them out and put them in the current opposite where we took them out as closely as we could.

1834 The wind was mostly upstream. The first day the wind was upstream, mostly from the right bank. The second day it was partly from the right bank. The third day we had a higher wind.

Q. Did they seem to dritf off toward the bank in the direction in which the wind was blowing?

A. Well, I think it had a kind of tendency to draw them over, at times. The river was very high—out all over the bottoms. When there was considerable wind there were waves in the current of the Illinois river, sometimes quite rough.

1835 Q. When the waves struck these floats, it seemed to knock them over in the direction which the waves ran, didn't it, a little?

A. Yes, that had a tendency to work that way somewhat. There was a visible effect of that character. When the wind blows upstream and the floats are floating down-stream, I don't think the wind would have very much effect on them—not the wind I encountered.

THOMAS F. REED: Live in St. Louis. Am rod man in the water department. Took part in observations, the object of which was to determine the velocity of the flow of the Illinois river last March.

1836 I covered from Lockport to Morris and from seven miles above Henry to Chillicothe. Those two portions were assigned to me. I started two floats at the Bear Trap dam on the 16th of March. From Lockport to Joliet, it took me

1837 two hours and 15 minutes. It took me 3 hours 35 and one-half minutes to go two miles and a half, about, above Millsdale. It took me 18 hours and 20 minutes to go from Lockport to Morris.

CROSS EXAMINATION by Judge Johns:

1841 At Ninth street bridge at Lockport, the gauge on the bridge read 16.7. On the 18th of March, at the mouth of Jackson creek, I read the gauge 81.55. Three miles below Millsdale 81.1. On the 19th of the month on the E., J. & E. railroad bridge 87.7. The Lacon wagon bridge was 18.7 feet.

1842 The river was very high. The wind caused the floats to move out of the channel. The wind would drive them right into the shore right along. The wind was generally across-stream and up-stream part of the way. The wind would blow the floats towards the shore in the direction the wind was blowing.

1843 On the second section that I was working, the river was very wide and the dams were all submerged with water. The wind had a free sweep. The water was quite rough all the time. The waves ran a foot high and more. When I had to take the floats out they had drifted in the direction in which the waves were running.

1844 L. B. ENGLISH, examined by Mr. Jeffries:

Live in St. Louis, am a law clerk in the city counselor's office of St. Louis.

Q. I will ask you if you have done anything with reference to the collection of typhoid death rates in various cities along the Mississippi to the north of St. Louis, in the last two or three months?

A. Yes, sir. I examined Minneapolis, St. Paul, Dubuque, Des Moines, Keokuk, Burlington, Hannibal, Quincy and Fort Madison. This was done commencing on the 6th of April and extending over a period up to and including April 15th this year. I went to Minneapolis first.

1845 I examined the records to determine the deaths per month and year from typhoid fever and the total number of deaths.

MR. TODD: I object on the ground that the records are the best evidence and on the additional ground that anything that he might say is here hearsay and is not competent.

I examined the records in the office of the Health Commissioner of Minneapolis to ascertain the deaths from typhoid fever and the total number of deaths from all causes. I have got those by the month beginning with January 1, 1893, up to and including December, 1902.

MR. TODD: I object to the question on the ground that the records are the best evidence and it is incompetent for this witness to testify to what the records disclose. In order to save time, will it be understood that this objection goes to all of this?

GENERAL CROW: Yes, sir, that will be understood to apply to all this class of testimony.

1846 (Witness gives number of deaths from typhoid in Minneapolis for years 1893 to 1902 inclusive.)

1850 On the following day I made a record of the deaths from St. Paul. (Witness gives same statement as to St. Paul.)

1854 I went to Prairie du Chein, but the records were incomplete, and they had only been taking them since the State law was passed requiring the clerk of the city to make them, and he had only been making them a short time. That place has a population of 3,500. Went to Dubuque, Iowa. (Witness gives number of deaths from typhoid in Dubuque by months from 1893 to 1902, inclusive.)

1858 Next is Des Moines, Iowa. (Same testimony.)

1862 From there I went to Burlington, Iowa. (Same testimony.)

1865 From there I went to Fort Madison. The records had
only been kept a very short time, and they commenced
with the year 1900. In 1900 they had four deaths, in
1866 1901 no deaths from typhoid reported. The law in Iowa
is that all deaths must be reported to the city clerk, and
he keeps a record of them. It was from this record I got this.
From January 1 to March 31, 1903, they had no deaths from
typhoid. From there I went to Keokuk, Iowa. (Witness gives
number of deaths from typhoid fever by months from 1893 to
1902, inclusive. I collected these figures from the rec-
1870 ords themselves. The next place I went was Quincy. I

made the same character of examination at Quincy as I did at the other points. (Witness gives number of deaths from typhoid fever by months from 1893 to 1902, in-
1874 clusive.) The next point was Hannibal. (Same testimony.)

1878 CROSS-EXAMINATION by Judge Johns:

These records themselves were kept in tabulated form in all the cities with the exception of Fort Madison. They gave the cause of death and age, birthplace and deathplace and burial place, and all those sort of things. In each one of those towns when I found those records they had persons and clerks as custodians of those records. In some cities that I took in—two or three places—the records were kept by the city clerk. In larger places they were kept by the health commissioner, but in all these places except Fort Madison they were in the custody of some officer appointed for the purpose of keeping the records.

1879 CROSS-EXAMINATION by Judge Springer:

I did not examine the records at Davenport, Iowa, or at Rock Island, Illinois. Rock Island is a large city. I did not examine the records at Galena. In each instance I took account of the population at the time I took the records—that is, the census of 1900. I found upon some of these records a statement as to the number of cases of typhoid that were treated—that was in one or two places—but they told me it was not accurate, as it depended upon the physicians to report them, and as a rule they were not sufficiently accurate to make any complete record from.

CROSS-EXAMINATION by Mr. Todd:

1880 All I have testified to I have simply got from the inspection of the records, copying from the records at the different places I have indicated.

1881 CROSS-EXAMINATION by Judge Springer:

In the cities of Des Moines, Burlington, Minneapolis and Dubuque I have the certificate of the clerk as to the correctness of those figures.

J. L. VAN ORNUM recalled, examination by Mr. Woerner.

1882 I have taken samples of the waters of the Mississippi
and Missouri rivers recently for the purpose of examination. On the 10th and 12th of April samples of water were
taken at sections noted on this sheet (referring to map), one
section being just above the confluence of the Missouri
and Mississippi rivers in the Mississippi river, another above
the same confluence in the Missouri river, another section in
the Mississippi river below the confluence of these two rivers,
and a fourth one about a thousand feet above the water works
intake. These samples were taken for the purpose of sending
to Mr. George C. Whipple, at Brooklyn, for turbidity examination. Duplicates of each sample were retained in St. Louis.
For distinguishing the samples at the time of taking, a tag was
tied about the neck of each bottle, on that tag being a capital
letter to distinguish the section as noted here (referring to
map), section I being close to the intake and section C
1883 also in the Mississippi river below the confluence of the
Mississippi and Missouri, section M in the Mississipi
above the mouth of the Missouri, and section B in the Missouri
river above the confluence. These were all cross sections, locations being kept on each cross-section from 1 to the highest
number, No. 1 always being towards the right bank of the river
—toward the Missouri shore. The number of samples taken
from each cross-section are indicated on this same sheet. There
were three points on section B in the Missouri river, and there
was one sample taken at a ten-foot depth at each of these three
points.

1884 This map that I have in my hands is a correct indication of the number of points at which samples were taken
at each location. It shows the current or the direction of the
river, of the flow of the respective rivers in so far as it may
be indicated on the map. That red line, as near as may
1855 be, indicates what may be called the channel line, or the
deepest water throughout the length of the Mississippi,

as shown on the sheet. (Map offered in evidence as complainant's Exhibit 44.)

MR. TODD: I object to the introduction of the map, in regard to what the map itself indicates, on the ground that it is not a correct condition that exists in the Mississippi river to-day, as the map was made in 1880, and has been stated by the witness in the other examination as not being correct as of to-day. I object on the further ground that the red line indicating the channel is placed upon the amp by the witness, and there is not sufficient evidence in the record to justify that that
is the channel to-day as indicated by the red line. My
1866 ascertainment of the channel is based upon soundings
marked upon this map at the time it was made by the
government officials.

JUDGE SPRINGER: We object to it as not showing the channel at the present time.

MR. TODD: I want to make a further objection. I object to the note that is placed on this map at the northwest corner, and signed J. L. Van Ornum, as being no part of the map.

CROSS-EXAMINATION by Judge Johns:

These samples were taken under my direction. (Witness
states how samples were taken.)
1887 Part of the samples were taken on the 10th of April
and part on the 12th. Section I, for instance, the distance between the various stations numbered from 1 to 12 is 400 feet. Section 1 is 300 feet from the Missouri shore. That distance was ascertained by sextant angle taken between transit placed on shore and the intake tower. We took three samples at station 1, section I, at six inches, ten feet, and I am
not positive whether the lowest was 30 feet now.
1890 Chouteau's slough is this (indicating on map).

Q. Was it at one of those places, where the word "sand" is, that you took out one of the floats and placed it back in the river, to which you testified the other day?

A. Somewhere along there. It was, I think, about a half a mile to the northeast, as I recollect it.

Q. If the float had gone down that chute it would probably never have gone anywhere near the intake?

A. Probably not.

CROSS EXAMINATION by Mr. Todd:

1891 This map, according to the notes placed upon the sheet by the Mississippi River Commission, was made when the stage of water was comparatively low. The stage of the Mississippi at the time I collected these samples was higher. The map was made at stages varying evidently from four feet above to ten feet above the low water stage. My impression is that the stage of water when we took the samples was 15 and 20 feet above the low water stage. The channel at high water is very often more or less different from the location of the channel at low water. The currents of a river are generally increased by high water. They do not run the same in certain places, as far as direction is concerned. High water has a tendency to change the currents in a river, especially where the channel passes from one side of the river to the other.

1893 Q. Is there anything on this map which indicates the direction of the currents at the stage of water that you found at the time you made your experiments?

A. Only in a general way.

1894 The rate of current at these points where samples were taken would be necessary to know, in order to figure the volume of water passing a given point. That I did not escertain. The current flows most rapidly at the top.

1895 It is a fact that in the Mississippi river channel of today might not be the channel of six months hence. I do not know whether the channel indicated here, by the red line on this map, is the true channel of the Mississippi river today. I have no scientific knowledge on the subject of what is the true channel today in the river.

1903 GEORGE CHANDLER WHIPPLE, examined by Mr. Woerner:

I reside in Brooklyn, New York.

1904 My official title is that of biologist and director of Mount Prospect Laboratory of the department of water supply, gas and electricity of the city of New York. I have been in that position since 1897, except that when I began at that time, I was employed by the city of Brooklyn and since then, there has been a consolidation with New York City. (States his 1909 professional training and experience.) I have had occasion to make microscopic examinations of samples of the waters of the Illinois, Mississippi and Missouri river. In October and November, 1901, I made microscopic examinations from, I think it was 136 samples, some from Lake Michigan, Drainage canal, Illinois river, tributaries of the Illinois, Mississippi river above Grafton, Mississippi river at Alton, Missouri river at Bellefontaine, Mississippi river at the Chain of Rocks and at the Illinois shore opposite the Chain of Rocks and settling basins of the St. Louis waterworks. These samples were sent to me at Mount Prospect laboratory in Brooklyn by express. They were marked so as to identify their source. They seemed to be in good condition for the purpose of microscopic examination.

1910 I examined all of them microscopically and in some of them I determined the turbidity and color. I examined them microscopically in order to determine the number and character of the microscopic organisms present. Strictly speaking, all very minute organisms may be called microscopic organisms but all water analysis have come to understand by the term "microscopic organisms" those minute forms of life which are too small to be readily identified without the use of a microscope, but which are large enough so that they do not need to be studied by artificial cultures as we study bacteria. For example, the microscopic organisms belong, some of them, to the plant kingdom and some of them, to the animal kingdom, although these low forms of life it is somewhat difficult to draw the distinction between animals and plants. In the water that I received, some of the organisms found might die out during the period of transit ,others of them might possibly develop during transit while others still would probably remain unchanged.

1911 They would not increase in number neither would they disintegrate to such an extent as to be unrecognizable. I have tabulated the results of the observations and the microscopic examinations which I made and I have with me these tables which contain the results. I have here a table which I have marked table zero, which gives the results of the microscopic examinations made from samples of water said to be collected from Lake Michigan, five of these samples being labeled as coming from the Lake View crib, three as coming from the Carter Harrison crib, and two as coming from the Four Mile crib. At the top of the table is a line giving the number of the sample, and I may explain that the samples as they were received, were given a serial number, and that these numbers in this line refer to those serial numbers. Beneath the line giving the number of the sample, is a line giving the locality from which the sample was collected, and beneath that a line giving the depth in feet at which the samples were collected, and beneath that a line giving the date of collection. Then in vertical columns I have placed at the left the name of the group of organisms found in the sample. In the second vertical column are the names of the genera found, and in the succeeding columns are the numbers of those genera which were found expressed in terms of standard units of organisms per cubic centimeter. Near the bottom there are two lines, one giving the total microscopic organisms, which numbers are the summation of the numbers given in the vertical columns, and then the last line giving the amount of amorphous matter which represents the amount of matter without form, simply, you might say, dirt, almost. Matter which is not recognizable as an organism; also expressed in terms of standard units per cubic centimeter. And I may say that this term "standard unit per cubic centimeter" is designed to show the relative bulk of these organisms present. In some cases, one standard unit corresponds with one organism. A standard unit as it is used is a unit of superficial area equal to 400 square microns, one micron being equal to 1-1000 of a millimeter. The advantage of using this unit of a standard unit instead of numbers is that the organisms differ in size and it is our intention in these analyses to express, as far as possible, the relative bulk of the different organisms present, in order that one may be compared with another.

1912 What I have just said applies to all of the tables, as I used the same standard and measure.

(Witness gives descriptions of various micro-organisms found in Lake Michigan, as indicated on table zero.)

1913 The total number of microscopic organisms expressed in the usual forms of standard units per cubic centimeter varied fom 576 to 1,656.

1914 The sheet that I now present is known as plate No. 1, and it contains the results of examinations of samples said to be collected from the drainage canal. The first four were marked Paulina Street and the last six were marked Bear Trap Dam, Lockport. The general arrangement of the sheet is similar to that of sheet No. zero. (Witness describes micro-organisms found in these samples.) The total numbers or organisms varied from 644 to 2,750.

1915 Plate No. 2 contains results of six samples from the Des Plaines river at Lockport above the entrance of the drainage canal. It wil be seen by this sheet that the organisms in general were much less numerous than in Lake Michigan or the Chicago drainage canal. The total number of organisms varied from 24 to 126, excepting on November 26, when there were 2,316. Plate No. 3 contains results of examinations from the various tributaries of the Illinois river. It will be seen that these tributaries vary considerably in the number of microscopic organisms found. For instance, the total numbers varied from 20 to 11,296. It will be noticed that the synedra and tabellaria which were so commonly present in the Lake Michigan water and in the water from the Chicago drainage canal are here only sparingly found.

1916 Plate No. 4, samples received from the Illinois river, three miles above Peoria. This sheet represents the results of six examinations. Plate No. 5 is Illinois river at Beardstown.

1917 Plate No. 6 represents results of samples collected from the Illinois river at Grafton, there being seven such analyses reported. Plate No. 7 represents results of seven examinations from samples from the Mississippi river above Grafton. Plate No. 8 shows results of six samples collected from the Mississippi at Alton.

1918 Plate No. 9, five examinations of samples collected from the Missouri river at Fort Bellefontaine. It will be seen that the organisms in the Missouri river were far less numerous than in the Mississippi river. Asterionella and tabellaria, which were observed in Lake Michigan and in the samples from the Illinois river and the Mississippi river at Alton, were not found at this point. Synedra were found.

1919 Table No. 10 represents the results of examinations of seven samples collected from the Mississippi at a point near the Illinois shore opposite the intake. The total number of organisms varied from 1,588 to 8,344. Plate No. 11 represents the results of seven examinations of samples collected at the intake. Synedra were present in three out of the seven samples, and the total number of microscopic organisms varied from 310 to 1,880.

1920 Table No. 12 represents the results of two examinations from samples collected at the settling basins of the St. Louis water works. Plate No. 13 represents results of examinations of twelve samples collected from the Mississippi river at a cross-section just above Alton on November 12, 1901.

1921 Plate No. 14 gives results of microscopic examinations of samples collected from the Mississippi river at a cross-section just above the Chain of Rocks. The arrangement of these samples in the cross-section from 1 to 11 being from the Missouri shore toward the Illinois shore.

1922 (Charts offered in evidence as complainant's Exhibit No. 46, with sub-numbers 1 to 15, inclusive.

A diatome is a unicellular plant, and perhaps its most important difference from other unicellular plants is the fact that its cell wall is so impregnated with silica that it is practically an indestructible thing. That is, a diatome might be described as a little plant cell made of glass. The living matter lies within this silicious cell, and after the death of the cell the walls of the cell remain just as they appear during life. In fact, they may be considered as fossil remains of a plant, and there are in existence to-day geological deposits which are composed almost entirely of diatomacious cells.

Q. Are they considered more hardy and more likely to survive the voyage from Lake Michigan down the various water courses to the intake at St. Louis than the other microscopic organisms, or not?

A. Yes, sir. These cells being indestructible, or practically so, could be identified after a long passage through the river, and this cell wall being a strong protection to the cell, offers more favorable resistance than many of the microscopic plants, such, for example, as the blue-green algae or the green algae, even.

Q. Where are those diatomes most likely to be found?

A. Diatomes are likely to be found in almost any kind of fresh water, but there are thousands of species of diatomes, and the particular diatomes with which we are concerned in those examinations, namely, asterionella, synedra, melosira, cyclotella, stephanodiscus and the others mentioned, are more commonly found in ponds and lakes and such bodies of water than they are elsewhere. These organisms just enumerated, or these diatomes just enumerated, are not as likely to be found in the waters of running streams, unless these streams are fed from lakes or ponds or similar bodies of water.

1923 Experience has shown that these organisms would not be likely to be found in streams tributary to the Illinois river excepting so far as these streams are fed by lakes or ponds.

MR. TODD: I move to strike out the answer.

It is my opinion that the diatomes in the Illinois river above the point where it enters the Mississippi river at Grafton came partly from Lake Michigan and partly from the tributaries of the Illinois river; that the waters of the Mississippi river from the various points below Grafton came partly from the upper Mississippi, from Lake Michigan and from the tributaries of the Illinois river, my answer being understood as to refer to the diatomes as a class and without reference to particular genera or species.

1924 There was an organism which I will describe as synedra pulchella variety sub-prolongata, which was found at the intake of the waterworks at the Chain of Rocks, and which was found also in the water of Lake Michigan, but was not found in the water of the Missouri river or the water of the upper Mississippi river, or in any of the tributaries of the Ilinois river, unless we consider the Chicago drainage canal as being a tributary.

1925 (Witness reads table representing averages of all examinations made at each point enumerated for the entire period covered by the observations.)

It contains the average results of the number of most important diatomes present at the various places between Lake Michigan and the settling basin of the St. Louis water works, where samples were collected. It gives the names of the diatomes and the average number of each for each place. I notice from this table that certain diatomes are especially characteristic of certain waters. Take the first on the table, synedra; the conclusion I draw from the results shown there is that the sixteen synedra which were found in the intake of the St. Louis water works came not from the Missouri river nor from the Mississippi river at a point above Grafton, but rather from the Illinois river at Grafton, and if we consider that there

1927 were 577 synedra in Lake Michigan, with only an average of 17 per cubic centimeter in all the tributaries of the Illinois river, I should conclude that the chances were that the sixteen synedra found at the intake, or most of them, came from Lake Michigan. As to the next one, the tabellaria, the conclusion I would draw from the table is that in all probability the tabellaria found in the settling basin of the St. Louis water works and at a point in the Mississippi river near the Illinois shore came not from the Missouri river or from the Mississippi river at a point above Grafton, but from Lake Michigan by means of the Illinois river, and not from any of the tributaries of the Illinois. Let us consider the melosira.

1928 The conclusion from the figures shown on the table is that for the most part the melosira found at the intake of the St. Louis water works and at the Mississippi river near the Illinois shore were derived not from the Illinois river or from Lake Michigan or from any of the tributaries of the Illinois, but rather from the Mississippi river above Grafton. Now consider the cyclotella, the conclusion being that these cyclotella found at the intake of the St. Louis waterworks at the Chain of Rocks came for the most part, not from the Missouri river, but from the Mississippi river and the Illinois river, and only to a slight extent from Lake Michigan. The cyclotella found in the Illinois river at Grafton being derived not from Lake Michigan, but from one or more of the tributaries. Now consider the astrionella, the conclusion being that for the

1929 most part the asterionella found at the intake of the St. Louis waterworks and at the Missouri shore, or at the Illinois shore opposite the Chain of Rocks, were derived not at all from the Missouri river, but chiefly from the Mississippi river above Grafton, but in part from the Illinois river and its tributaries and Lake Michigan. Now the stephanodiscus, from the table I conclude that of the stephanodiscus, or that the majority of the stephanodiscus found at the intake of the St. Louis waterworks and at the Illinois shore oposite the Chain of

Rocks were derived not so much from the Missouri river or the Illinois river as from the Mississippi river above Grafton.

The synedra found in Lake Michigan belong to the species pulchella and variety sub prolongata, while the synedra found in the tributaries of the Illinois river were either the synedra lonslotta or the synedra pulchella variety curta. The synedra pulchella are very easily distinguishable from the synedra lonslotta, because of the different shape, while the synedra pulchella, variety sub prolongata differ from the synedra pulchella variety curta in their size; the sub prolongata being in round numbers, twice as large as the variety curta. All three of these forms of synedra are very easily distinguishable under the
powers of the microscope used in the examination.
1930 This would enable me to distinguish which came from
Lake Michigan and which came from other sources when they were taken from the waters at the intake. I found the synedra pulchella variety sub prolongata at the intake of the St. Louis waterworks I think on November 12, if I recollect the date correctly. So far as all of my examinations show I should say that they came from Lake Michigan. I made a chart of the comparative number of these different diatomes in various sections —that is, those which were most prominent. This chart depicts graphically the results of my investigations. I present first, diagram No. 1, which gives the results of the determinations of synedra pulchella, per cubic centimeter, at the various places
between Lake Michigan and the intake of the St. Louis
1931 waterworks. The next diagram is No. 2 and is drawn by
the same plan as the preceding and shows the number of tabellaria fanistrata at the points enumerated on the diffenent sections.

1932 The next diagram being No. 3, shows the number of stand-
ard units of microscopic organisms actually discharged with the pollution by the various towns between Lake Michigan and noted at the bottom of the diagram, and states the organisms included in the above.

1933 This diagram shows that the organisms were very few in Lake Michigan, and that they were quite numerous in the Chicago Drainage canal and the Illinois river above Grafton, and from the Missouri river at Bellefontaine and that they were found in the Illinois river or rather in the Mississippi river at the Illinois shore opposite the Chain of Rocks and at the intake of the St. Louis waterworks.

The next diagram shows the number of melosira granulata in the Illinois river at Grafton did not exceed 24 per cubic centimeter standard units, and in the Missouri river at Bellefontaine, they did not exceed 60 per cubic centimeter, the quantity being so low they would scarcely appear on this sheet. The results indicate that during the period covered by the investigation there was a gradual decrease in the number in the Mississippi river at Grafton and that this decrease was also noted at Alton in the Mississippi river and at the Illinois shore opposite the Chain of Rocks, and also at the intake of the waterworks at the Chain of Rocks.

Diagram No. 5 shows the number of cyclotella operculata at various points in the Mississippi river and at the Illinois river at Grafton. The note states that during this period the cyclotella operculata did not exceed 60 per cubic centimeter in the Missouri river at Bellefontaine, but the results indicate that during the latter part of November there was an enormous increase in the cyclotella operculata in the Illinois river at Grafton, the numbers being so great it could not be shown upon the scale of this diagram; and that this increase was also noted at Alton at the Illinois shore, Chain of Rocks, and at the intake of the St. Louis waterworks.

Diagram No. 6 shows results of examinations made of samples collected at 12 points in the cross-section across the Mississippi river above Alton. It shows the results of microscopic organisms and it also shows the results of certain turbidity and color observations which I have not yet put in the testimony. The upper line shows the turbidity of the water at the different stations expressed in terms of the silica standard.

1935 The second section shows the color of the water at the different stations expressed in terms of the platinum coblat standard.

The next section shows the number of microscopic organisms characteristic of the Mississippi river, indicated by lines of different character, the full line referring to the total organisms; the melosirt being expressed by the dash line, the cyclotella by the dotted line and the stephanodiscus by the dot-dash line.

The last section on the sheet shows the microscopic organisms characteristic of Lake Michigan. The synedra expressed by the full line and the tabellaria expressed by the dash-line. The results show that the turbidity was fairly constant across the stream, but that it was lower on the eastern shore than on the western.

The turbidity of the water means its opacity to light, or its opacity or opposition to the passage of the rays of light and is a measure of the suspended matter present. Observations of turbidity are frequently made instead of determinations of suspended matter because of the much greater convenience of the method. The diagram shows that there was in general a gradual decrease of color from the Missouri shore toward the Illinois shore and that the color was particularly low near the Illinois shore. The diagram also shows that the melosira, which, as has previously been offered in testimony, were especially characteristic of the waters of the Mississippi river above Grafton, decrease generally from the Missouri shore towards the Illinois shore, while the cyclotella, which were found in both the Illinois river and the Mississippi river, but were more abundant in the Mississippi river at the time when the cross-section was made, were fairly constant across the river excepting near the Illinois shore, while the stephanodiscus were nearly uniform across the stream, but showed a slight tendency to decrease toward the Illinois shore.

1933 This diagram shows that the organisms were very few in Lake Michigan, and that they were quite numerous in the Chicago Drainage canal and the Illinois river above Grafton, and from the Missouri river at Bellefontaine and that they were found in the Illinois river or rather in the Mississippi river at the Illinois shore opposite the Chain of Rocks and at the intake of the St. Louis waterworks.

The next diagram shows the number of melosira granulata in the Illinois river at Grafton did not exceed 24 per cubic centimeter standard units, and in the Missouri river at Bellefontaine, they did not exceed 60 per cubic centimeter, the quantity being so low they would scarcely appear on this sheet. The results indicate that during the period covered by the investigation there was a gradual decrease in the number in the Mississippi river at Grafton and that this decrease was also noted at Alton in the Mississippi river and at the Illinois shore opposite the Chain of Rocks, and also at the intake of the waterworks at the Chain of Rocks.

Diagram No. 5 shows the number of cyclotella operculata at various points in the Mississippi river and at the Illinois river at Grafton. The note states that during this period the cyclotella operculata did not exceed 60 per cubic centimeter in the Missouri river at Bellefontaine, but the results indicate that during the latter part of November there was an enormous increase in the cyclotella operculata in the Illinois river at Grafton, the numbers being so great it could not be shown upon the scale of this diagram; and that this increase was also noted at Alton at the Illinois shore, Chain of Rocks, and at the intake of the St. Louis waterworks.

Diagram No. 6 shows results of examinations made of samples collected at 12 points in the cross-section across the Mississippi river above Alton. It shows the results of microscopic organisms and it also shows the results of certain turbidity and color observations which I have not yet put in the testimony. The upper line shows the turbidity of the water at the different stations expressed in terms of the silica standard.

1935 The second section shows the color of the water at the different stations expressed in terms of the platinum coblat standard.

The next section shows the number of microscopic organisms characteristic of the Mississippi river, indicated by lines of different character, the full line referring to the total organisms; the melosirt being expressed by the dash line, the cyclotella by the dotted line and the stephanodiscus by the dot-dash line.

The last section on the sheet shows the microscopic organisms characteristic of Lake Michigan. The synedra expressed by the full line and the tabellaria expressed by the dash-line. The results show that the turbidity was fairly constant across the stream, but that it was lower on the eastern shore than on the western.

The turbidity of the water means its opacity to light, or its opacity or opposition to the passage of the rays of light and is a measure of the suspended matter present. Observations of turbidity are frequently made instead of determinations of suspended matter because of the much greater convenience of the method. The diagram shows that there was in general a gradual decrease of color from the Missouri shore toward the Illinois shore and that the color was particularly low near the Illinois shore. The diagram also shows that the melosira, which, as has previously been offered in testimony, were especially characteristic of the waters of the Mississippi river above Grafton, decrease generally from the Missouri shore towards the Illinois shore, while the cyclotella, which were found in both the Illinois river and the Mississippi river, but were more abundant in the Mississippi river at the time when the cross-section was made, were fairly constant across the river excepting near the Illinois shore, while the stephanodiscus were nearly uniform across the stream, but showed a slight tendency to decrease toward the Illinois shore.

The syndera which were characteristic of Lake Michigan were not present in samples 1 to 5 and were most abundant in sample 7; while tabellaria, which also was especially characteris of Lake Michigan, were not found in samples 1 to 4, or in samples 7 and 8, but were found in the other samples.

This last diagram is No. 7, and it shows the results of the observations of the samples taken in the cross-section of the Mississippi river about one mile above the Chain of Rocks, and it shows the turbidity of the water at each station, the color at each station, and there is a line showing the comparative abundance of melosira, cyclotella and stephanodiscus organisms which at that time were especially characteristic of the Mississippi river above Grafton, and a line showing the synedra and tabellaria organisms which at that time were especially characteristic of Lake Michigan. These samples were collected on November 10, 1901. These are the turbidity observations shown on this diagram, and indicate a progressive decrease from the Missouri shore towards the Illinois shore, while the color progressively increases from the Missouri shore towards the Illinois shore. The lines at the bottom of the diagram show the progressive increase in the melosira, cyclotella and stephanodiscus, speaking in a general way, from the Missouri shore towards the Illinois shore, while the same is practically true of the synedra, an organism especially characteristic of Lake Michigan. The tabellaria, which was characteristic of Lake Michigan, was not found west of station 7. It will be noticed, however, that all of these organisms which were characteristic of the Mississippi river water were found at
1937 station 1, and that the synedra, which was characteristic of the water of Lake Michigan, was also found at stations 1, 2, 3 and 4. (Diagrams offered in evidence as complainant's Exhibit 47, sub-numbers 1 to 7, inclusive.) I made calculations as to the relative amount of water coming from the Mississippi and Missouri rivers into the intake. I assume, for the purpose of this calculation, that the samples which were collected at the Missouri river at Bellefontaine represented the

character of the water in the Mississippi river, and that the samples which were collected in the Mississippi river at Alton represented the character of the Mississippi river just above the point, or above the point where the Missouri river enters the Mississippi river just above the point or above the point where the Missouri river enters the Mississippi, and I compared the average results of similar organisms found in the water at the intake of St. Louis waterworks. I concluded that on an average 32 per cent of the water which entered the intake of the St. Louis waterworks was considered as Mississippi river water and that 68 per cent of the water was Missouri river water.

1939 I made turbidity observations and observations of color in the samples taken from the two cross-sections, one just above Alton and the other one mile above the Chain of Rocks, to find the relative turbidity of the water across the stream at the different points and the relative color across the stream at the different points. (Witness gives results of turbidity and color of twelve samples in cross-section taken in the Mississippi river above Alton November 12.) When I say that the turbidity of a sample is 18 it means that that sample is just as turbid as it would be if it contained 18 parts per million of what we call silica standard, or 18 parts per million of finely divided silica, which is prepared according to a definite formula.

1940 The relative opaqueness would be arrived at by the turbidity, and the higher the number the greater turbidity, or the greater opaqueness. The color is measured by comparing the sample of water after removing the suspended matter, with arbitrary standards which are varied in color by the addition of different amounts of platinic chloride, and when I say that the color of the water is 34 it means that the color is as dark as an artificial solution which contains 34 parts per million of this platinum salt.

1941 (Witness gives results of examination of eleven samples in cross-section from the Missouri shore to the Illinois shore, one mile above the Chain of Rocks.

1942 I received some samples from Prof. Van Ornum during the month of April, 1903. They were received at my laboratory in Brooklyn on April 14 and April 16. I received 68 samples. These samples were tagged. I received a letter from Prof. Van Ornum, in which he stated that the capital letter M referred to a cross-section about one-quarter of a mile above the mouth of the Missouri river, across the Mississippi river, and that the serial numbers from 1 to 8 represented stations in that cross-section, beginning with the Missouri shore and running across to the Illinois shore, and stating further that the samples were spaced 200 feet apart, and also that the letter "b" meant that the sample was collected at a depth of ten feet below the surface. Upon each tag there were also figures indicating the temperature of the water in degrees Fahrenheit.

1943 I also received some samples marked "I," thirty-three bottles, with serial numbers from 1 to 12, that referred to a cross-section of the Mississippi above the intake at the Chain of Rocks. The serial numbers from 1 to 12 represented the stations across the river from the Missouri shore towards the Illinois shore, samples being taken 400 feet apart. The small letter "a" meant that the sample was taken at or near the surface. The small letter "b" indicated that the sample was collected at a depth of ten feet, and the small letter "c" that the sample was collected at or near the bottom of the stream.

1944 On April 16 I received three samples marked with a capital "B," with serial numbers from 1 to 3, followed by the small letter "b" in each case. These represented a cross-section of the Missouri river just above its mouth, No. 1 being near the south shore, No. 2 in midstream, and No. 3 near the north shore, also twenty-four samples marked with capital "C," with serial numbers from 1 to 8, and small letters either "a," "b" or "c." These I collected across the Mississippi river below the point where the Missouri river enters into it. Serial numbers ran from 1 near the Missouri shore to 8 near the Illinois shore, stations being 200 feet apart.

1945 I examined all the samples for turbidity.

1946 (Gives results of examination of samples "M," "B" and "C.")

1947 (Gives result of sample "I.")

1949 (Witness exhibits 12 bottles of water from complainant's exhibit 45, marked with capital letter "I" and explains method of ascertaining the turbidity of water.)

1950 Sample No. 1 is very much more turbid than sample No. 12 (referring to bottles Nos. 1 to 12 above referred to.)

1951 Comparing these samples as they stand before me, it is evident that there is a rather sudden decrease in the turbidity of the water from the Missouri shore toward the Illinois shore in the first four or five bottles and that from there on toward the Illinois shore, the difference in turbidity is comparatively small. My recollection is that the first sample was taken about 150 feet from the Missouri shore and that succeeding samples were taken at intervals of 400 feet in this cross-section.

1952 I prepared diagrams to show graphically these cross-sections of the rivers according to the samples that were taken by Prof. Van Ornum, that is, for three out of four—sections "I," "M" and "C." This diagram which I hold in my hand represents graphically the results of the turbidity observations made at section "I" already put in evidence, taken from the samples of water furnished me by Prof. Van Ornum in April, 1903, that is, about one-quarter of a mile above the Chain of Rocks. There are three lines upon this diagram, the line represented by the dots and dashes refers to the sample taken just below the surface of the stream, that would be the samples marked with a small letter "a," the full line refers to those samples collected at a depth of 10 feet, marked with small letter "b," the dash line represents samples collected at the bottom, which were marked with a small letter "c." In the last three samples, the solid line and the dash line were the same, that is, the bottom sample was at a depth of 10 feet.

1953 I should say that the intake tower would lie approximately between stations 4 and 5 shown on this diagram. (Chart offered in evidence as complainant's exhibit 48.)

1954 The next diagram shows the observations made at section C, being a cross-section of the Mississippi river about one mile below the mouth of the Missouri. The diagram is drawn in similar manner to the preceding. (Offered in evidence as complainant's exhibit 49.) The diagram which I hold in my hand graphically represents the results of observations made at section M, being a cross-section of the Mississippi river, at a point about a quarter of a mile above the mouth of the Missouri. (Offered in evidence as complainant's exhibit 50.)

1955 (Charts of water analyses referred to by witnesses Teichmann, Miller, Getz and others, containing 117 pages, offered for identification, to be known as complainant's exhibit 1 for identification.)

CARL UNGAR, examined in chief by Mr. Woerner:

Attorney at law. Resides in St. Louis. Has made investigation as to typhoid statistics of towns in Illinois river valley.

1956 Left St. Louis by instruction of City Law Department on or about April 7th. Visited Springfield and found the records there in poor shape. Only got three years—1900, 1901 and 1903. (Gives number of deaths per year in Springfield.) Next went to Bloomington. (Gives results of examination of records, showing deaths in Bloomington from 1893 to 1902.)

1958 (Statement as to Peoria and Ottawa.)

1959 (Decatur.)

1960 (Joliet.)

1961 (Pekin.) I found the reports very incomplete.

1962 (Elgin and Aurora.) They hadn't any records worth speaking of.

1963 (Havana.) I took what I could get by the year.

1966 **WILLIAM H. GETZ, re-called for direct examination by Mr. Jeffries:**

This is a table of percentages of the Missouri and Mississippi river water at the intake of the St. Louis waterworks. These calculations are based upon the daily estimation of total solids in samples collected at Bellefontaine, the intake and at Hartford, covering a period from January 23d to October 11, 1900. (Witness examined in regard to complainant's exhibit 1 for identification, stating how they were prepared and what they represented, in order that they may be introduced in evidence.)

1969 CROSS-EXAMINATION by Judge Johns:

On the charts that were made, the gauges were put, but there were no numerical figures put on the sheets that these were taken from. There was no need of the stages of the river for the purpose of assisting in this conclusion. (This exhibit being offered for the purpose of showing the mixture of the water at the intake.) There is nothing on this table of percentages which shows that on the 7th of February when the percentage of Mississippi river water in the intake was 100 and the percentage of the Missouri river water was zero, as to the state of the gauges at that time. Such figures were put on the charts that have been exhibited covering the weekly averages but not in the tables.

1971 These calculations do not depend, in any way, on the stage of the river. Stages of the river may affect the result, but there was no use made of them in the calculations.

1972 GENERAL HAMLIN: I object to the introduction of the table unless complainant offers to follow it up with proof of rain-fall, and so forth, on the lower Illinois river and the Mississippi and Missouri at the time these calculations were made.

GENERAL CROW: At the proper time, we will offer such statistics on the question of rain-fall and water gauges in the Missouri, Mississippi and Illinois rivers as we think proper to offer.

CROSS-EXAMINATION by Mr. Todd:

The date from which these percentages were figured was taken from the original note-books first and collected on to these charts, or on the tables and then it was taken from there for this special purpose. These figures were taken from the tables marked here as complainant's exhibit 1 for identification.

CROSS-EXAMINATION by Judge Johns:

1973 When I made these figures as to solids, I took them from the Missouri river at Bellefontaine and for the Mississippi at Hartford. I made the calculation for total solids. Well, there is always considerable variation in the total solids as found in the Missouri river at Bellefontaine, and those found in the Mississippi river at Hartford, and the total solids at the intake of the St. Louis waterworks was found to lie between those two, or approximately the same as either one of them, and by taking the difference in the total solids in the two rivers at those places, and interpolating the value of the total solids found at the intake, we find the percentage of the two rivers, which is represented by the mixture.

1974 CROSS-EXAMINATION by Judge Springer:

Now, for the month of January, 1900, I have presented here 25.75 as the average for all the samples we had during that month and that figure represents the average amount of Mississippi river water entering the intake during that period —about seven or eight days. This average amount of water from the Mississippi that entered the intake during those days in January which are here noted simply means an average which I have reached by estimating the total solids which I found in the waters of the two rivers, one at Bellefontaine and the other at Hartford.

1977 Q. The fact that at one time, during one month for instance, the average would be 25.75 and the next month would be 40.67, and for another month 60.29, and so on—they are variations which can only be explained from different stages of the river and the different conditions of the weather along the line of the rivers above the place where the samples were taken? A. Yes, sir.

RE-DIRECT EXAMINATION by Mr. Jeffries:

Q. Now, Mr. Getz, along the line of the questions propounded to you by Judge Springer, state what effect the fact of a flood in the Missouri river and a comparatively low water stage in the Mississippi river would have with reference to the correctness of arriving at the proportionate amounts or relative amounts of the two waters going into the intake?

A. It would have absolutely no effect.

GEORGE C. WHIPPLE, re-called for further direct examination by Mr. Jeffries:

1978 Have visited the Chain of Rocks and made myself personally familiar with that portion of the waterworks' plant of St. Louis which is located at that point. The approximate distance from the Missouri shore to the intake tower of the waterworks is about 1,500 feet. The intake tower is located a few hundred feet to the west of the channel of the Mississippi river at that point. I mean the center of the channel of the river—that is, the central thread of the main channel of the stream. It is about six miles from the intake tower to the mouth of the Missouri river. The Mississippi river, before it reaches the intake tower curves to the westward.

1979 (Witness explains the general features of the Mississippi river with regard to curves and directions of flow between the mouth of the Missouri and the intake tower, at the Chain of Rocks, as indicated on complainant's exhibit No. 44.)

1980 From my general knowledge of the subject of rivers and the effect of curves upon the currents of those rivers, it is my opinion that this curve which I have described, in the Mississippi river between the mouth of the Missouri river and the intake of the St. Louis waterworks would tend to allow, or would increase, or would be favorable to the mixture of the waters which come down the Mississippi river and the Missouri river.

1981 Judged from samples I have examined from section B and section M, I should say that the water in the Missouri river is much more muddy than the water in the Mississippi river and that it contains very much larger amounts of suspended matter. I also found that the water of the Mississippi river at Alton was more highly colored than the water of the Missouri river at Bellefontaine.

1982 In using this term I refer not to any substance in suspension but rather to substances in solution. I have observed that the amount of chlorine in the Missouri river was generally higher than that in the Mississippi river above the mouth of the Missouri. From the same sheets—complainant's exhibit 1 for identification, I also observe that ordinarily the amount of alkalinity in the Missouri river at Bellefontaine was higher than that in the waters of the Mississippi above the mouth of the Missouri.

If I should find certain forms of vegetable life which can be distinctly identified by well defined characteristics in the water of the Mississippi river above the mouth of the Missouri, and if at the same time, these organisms were absent from the water of the Missouri river itself, and if at the same time I should find them in the water of the intake tower of the St. Louis waterworks at the Chain of Rocks; it is my judgment that these organisms found at the intake tower of the St. Louis waterworks came from the water of the Mississippi river above the mouth of the Missouri river and that they were borne thither by the water of the Mississippi river above the mouth of the Missouri.

Q. Assuming that at times the water of the Mississippi river above the Missouri contains very little mud, and that the water of the Missouri river at the same time is highly charged with mud and further assuming that the water taken through

the intake tower at the Chain of Rocks, contains an amount of
mud intermediate in quantity between those of the two
1983 rivers before they unite?

A. It would be my opinion that the water found at the intake tower of the St. Louis waterworks, at the Chain of Rocks, was not entirely water derived from the Missouri river nor water entirely derived from the Mississippi river above the mouth of the Missouri, but was a mixture of the two waters.

Q. I hand you a table containing a transcript of the quantities of the total solid matter in the Missouri river at Bellefontaine, and the Mississippi river at Hartford and the water at the intake, which is a table read in evidence by witness Getz and ask you to explain the table and state whether or not the results as to the quantity of water of the respective rivers entering the intake at the Chain of Rocks, are determined by that table?

A. In looking over this table, I find that in general the total solids found in the samples at the intake were intermediate in amount between those found in the Mississippi river at Hartford and in the Missouri river at Bellefontaine and it is my opinion that it is possible from the figures given to calculate approximately the relative amounts of the water of the Missouri river and of the Mississippi river above the mouth of the Missouri present in the water at the intake of the St. Louis waterworks. I understand that the percentages obtained in the last two columns were obtained from the information given in the previous columns. Does that sufficiently answer your question, Mr. Jeffries? Q. Yes.

GENERAL HAMLIN: I move to exclude the answer for the reason that the witness did not make the table itself, or the table from which it was made, nor does he undertake to say that he has examined the samples or made analyses of the waters mentioned. His answer is simply to bolster up a table
made by some one else and not by him.
1985 It is my opinion that if the figures given in this table
represent the total solids in the water of the Mississippi

river at Hartford and the water of the Missouri river at Bellefontaine, and the water of the intake of the St. Louis waterworks, at the Chain of Rocks, if these figures are accurate representations of the total solids in the samples collected, and if the samples collected fairly represent the waters of the streams at the points named, then the calculations made by using these figures in obtaining the percentage of water of the Missouri river and of the Mississippi river above the mouth of the Missouri, in the water of the intake of the St. Louis waterworks, are reliable.

1987 My calculations showed from the samples that I examined that the percentage of Mississippi river water which was present at point 4 in section I was about 90 per cen that the percentage of Mississippi river water at point 5 in the same section was about 97 per cent. (Witness states metho of ascertaining these averages, on pages 1986 and 1987.)

1988 Assuming that when the waters of the Mississippi and Missouri unite at that junction, that there is no minglin of the waters with each other as they flow down stream, I should expect to find that in crossing the river from the Missouri shor to the Illinois shore at a point referred to by section "I" o complainant's exhibit 44, that there would be a sharp line o demarcation separating the waters of the Missouri on the wes shore from the water of the Mississippi on the east shore. N examinations which I have made have shown that such a shar line of demarcation existed and that can be illustrated by referring to samples of water collected at 12 points on sectio "I," numbered 1 to 12, beginning on the Missouri shor

1989 It is my opinion that the relative percentage of th waters of the Mississippi river and the Missouri river a the intake can be most readily determined from the total solid

Q. When considering cities having a population of 25,0 or more according to the census of 1890, what percentage increase to the population naturally resident upon the wate shed of the Mississippi, at the Chain of Rocks, is caused by t Sanitary District of Chicago diverting its sewage into t

Illinois river and becoming thereby tributary to the Mississippi?

GENERAL HAMLIN: That is objected to on the ground that it is not a proper basis of estimation upon which to base a proper conclusion as to this subject matter by an expert, and the further objection that the testimony is not relevant to the issue in hearing, made by the bill and answer.

Speaking generally the population is about double.

1990 If you consider the population of cities which have more than 4,000 population situated upon the watersheds of the Missouri, Mississippi and Illinois rivers, above the Chain of Rocks, but not including the population of Chicago, and if we add to this population, the population of Chicago, we should increase the populations as mentioned, by about 63 per cent.

(Objected to by Mr. Hamlin.)

1991 There is this custom among sanitarians, that when it is desired to determine the amount of sewage pollution which exists in a stream at any certain point, to consider the population dwelling upon the watershed above that point in cities which have 4,000 or more inhabitants and for this general reason we take it the country over. It has been found that in general, communities which have more than 4,000 inhabitants are ordinarily supplied with such public improvements as public water supplies and sewerage systems, while, in general, those communities which have less than 4,000 people are not ordinarily so supplied. In making those calculations, I have adopted the same means. It is about 23 miles by river from the mouth of the Missouri to the mouth of the Illinois.

I believe it is possible by analytical means to determine the percentage of the Illinois river water which is present in the Mississippi river at Hartford, for example. I also made such a calculation in order to determine the percentage of Illinois river water at Alton, as well as at Hartford. I made these calculations from the analyses shown upon the sheets which I hold in my hand and which form a part of complainant's exhibit 1 for identification. (Witness states method pursued in making such calculations.)

GENERAL HAMLIN: I move to exclude the answer as to the results obtained, as they are not expert's statements, but are statements of a fact determined from tables not made by the witness.

From these average figures, I have calculated the percentage of the Illinois river at the five points in the cross-section of the Mississippi river at Alton and at Hartford.

1994 (Witness states results of calculations at Hartford and Alton.)

This is a diagram which shows graphically the results, the average amounts of nitrites and chlorines at the cross-sections at Alton and Hartford, across the Mississippi river, for the period from October 30th to November 4th, from the period of October 30th to November 29th, in the case of the Alton cross-section and from November 4th to November 30th, in the case of the Hartford cross-section. It also gives in the lower portion of the diagram, a graphical illustration of the percent of the Illinois river at the two cross-sections.

1995 (Diagram offered in evidence as complainant's exhibit 51.)

Q. Mr. Whipple, assuming that at a certain time Lake Michigan water contained an organism called cynedra pulchella sub prolongata variety, and that this plant is not contained at corresponding times in any of the branches tributary to the Illinois river, nor in the upper Mississippi water at Grafton, nor in the Missouri river water, and further assuming that this plant was found at a corresponding time in the water at the intake tower at St. Louis, what in your opinion does that show?

MR. TODD: I object to the question on the ground that the assumptions have not been established in the evidence, especially as to the Missouri river.

It would show that this synedra pulchella variety sub prolongata was not derived from the water of the Missouri river or from the water of the Mississippi river above Grafton, or

from the tributaries of the Illinois river, but that it
1996 came from Lake Michigan and was borne thither by the
water from Lake Michigan.

1996 (Same question answered as to tabellaria.)

When the germs of typhoid fever are put into natural waters they will continue to live for several months, though in gradually decreasing numbers.

1997 From what I know about the life of the typhoid fever bacillus in the water, and from my knowledge of the conditions which exist between the Chicago Drainage canal and the intake of the waterworks of St. Louis, at the Chain of Rocks, it is my opinion that if typhoid fever germs exist in the sewage of Chicago, they will survive the passage down the Chicago Drainage canal and to the intake tower of the St. Louis waterworks at the Chain of Rocks under existing conditions. (The question to which this answer was given, assumes the water to reach St. Louis in ten and one-half days.)

1998 From personal observations to which I have testified (an inspection of the Chicago river, canal, and so forth) and assuming that the sewage and lake water passing through the Chicago river into the Drainage canal reaches the Mississippi at the Chain of Rocks, in ten and one-half days, it is my belief that typhoid fever germs coming from the sewers in Chicago, survive the passage through the Chicago Drainage canal, the Des Plaines river and the Illinois river to St. Louis. (Objected to by Mr. Hamlin and Mr. Todd.)

Under the conditions assumed (flood times) it is my judgment that a greater proportion of typhoid fever germs would reach the intake of the St. Louis waterworks from the Chicago Drainage canal when the time of transit was 8 days than when the time of transit was 10 1-2 days.

GENERAL HAMLIN: I move to exclude the answer on the same ground as previously stated.

1999 I believe from my general knowledge of typhoid fever epidemics that there are cases on record where such epidemics have occurred where the evidence shows that typhoid fever germs considered to have caused the epidemic, remained in natural water for at least 10 01-2 days prior to the entrance of the water into the service pipes of the community where the epidemic prevailed. The cases on record of this character are those which occurred at Detroit, Michigan and at Lawrence, Massachusetts.

MR. TODD: I move to strike out the answer as not being competent evidence.

2000 From my knowledge of existing conditions of the Drainage canal and the several connecting water courses between that canal and the intake tower of the St. Louis waterworks, it is my opinion that there does not exist any efficient work of artificial construction which continually insures the prevention of typhoid fever germs, which may enter the Chicago Drainage canal, from reaching the intake. (Objected to by Mr. Hamlin and Mr. Todd.)

Q. Assuming that between Jan. 17, 1900, and Dec. 31, 1902, as compared with the period from 1885 to 1899 inclusive, there had been no increase on an average in the number of deaths from typhoid fever in those cities situated upon the Missouri river, upon the Mississippi river above Grafton and upon the Illinois river and its branches, exclusive of the Chicago Drainage canal, and further assuming that the typhoid fever death rate in the city of St. Louis had increased about 54 per cent on an average during this period, over the previous period mentioned, and further assuming that there was no substantial change in the manner of treatment of the water supply of St. Louis and assuming further that since January 17, 1900, a large part of the sewage of Chicago has been passed through the Drainage canal and thence into the Des Plaines river, 2001 the Illinois river, the Mississipi river, and into the intake, and assuming further that some of the water of the Mississippi river would contain a certain amount of Illinois river water at the intake of the waterworks at the Chain of Rocks,—state what, if anything, in your opinion the Chicago sewage from the Drainage canal had to do with the increased typhoid death rate in St. Louis.

(Various objections by Mr. Hamlin and Mr. Todd.)

A. Under the assumption which you have mentioned, and if the conditions named are those which obtained, it is my judgment that the sewage of Chicago was the most probable cause of the increase of typhoid fever in the City of St. Louis which you mentioned.

1902 From my knowledge of existing conditions in the Drainage canal and the several connecting courses between that canal and the St. Louis waterworks, it is my opinion that no reliable and efficient natural agencies exist which can continuously insure the prevention of typhoid fever germs which may enter into the Drainage canal, from reaching the intake at St. Louis.

Q. Assuming that 106 barrels containing 40 gallons each of the culture of bacillus prodigiousus, etc., were emptied into the Drainage canal at La Monte, that at the time of this experiment this germ was absent in the waters under consideration in this case, and assuming that soon afterwards some colonies of bacillus prodigiousus on several occasions were found in samples of water taken from the intake tower at the Chain of Rocks, what, in your opinion, does this show? (Several objections by Mr. Todd and Mr. Johns.)

2003 It is my opinion that the origin of the bacilli found was the culture which was introduced into the Chicago Drainage canal. To judge from experiments which I have made and what I know generally on the subject, it is my judgment that the longevity of the typhoid fever and prodigiousus germs in natural waters is not greatly different. From my general sanitary knowledge, it is my judgment that the dejecta of typhoid fever patients would enter the sewage of Chicago—

GENERAL HAMLIN: That would, or does, did you say?

A. That do, I say, enter the sewers of Chicago, and that under the assumption mentioned, that the sewage of Chicago enters the Chicago Drainage canal, or has entered the Chicago

Drainage canal since its opening, since January 17, 1900, it is my judgment that the dejecta from the typhoid fever patients of Chicago enters via the sewers of Chicago, the Chicago Drainage canal, or the Chicago river, and the Chicago Drainage canal.

2006 GEORGE C. WHIPPLE: In my testimony yesterday I did not have at hand the average amount of chlorine in the water of the Illinois river above Grafton for the period between October 30, and November 29, 1901, which I used in calculating the percentage of Illinois river at various points in a cross-section of the Mississippi river at Alton. Upon consulting my notes I find that the average figure which I used was 20.3—this figure being an average of the results of daily chlorine determinations given upon one of the sheets in complainant's Exhibit No. 1 for identification. Neither did I have the figure for the average chlorine in the water of the Mississippi river above Grafton for the same period, and upon consulting my notes I find that the figure which I used was 3.9 parts per million of chlorines. This figure being an average of daily determination of chlorines given upon one of the sheets in complainant's Exhibit No. 1 for identification.

2007 I understand that those sheets are the results of examinations made by Teichmann and Keiser—under the direction of Mr. Teichmann.

2008 GENERAL HAMLIN: I move to exclude this statement or answer on the ground that it is a mere calculation testified to by this witness based upon tables that were not prepared by him and are not the subject of expert testimony.

Assuming that since January 17, 1900, a larger amount of the sewage of Chicago has entered the Des Plaines and Illinois rivers via the Drainage canal, than was previously the case, and assuming that water of the Illinois river containing such sewage, enters the Mississippi river and passes to the intake of the St. Louis waterworks, it is my judgment that since January 17, 1900, the water at the intake of the St. Louis waterworks has been relatively less safe for drinking purposes than prior to that time.

GENERAL HAMLIN: I move to exclude that answer for the reason the facts assumed in the question are not the facts as testified by complainant's witnesses and the records, so far.

It is my judgment that the most dangerous kinds of pollution of water supplies derived from rivers, lakes, ponds, or reservoirs, with reference to the safety of these waters for drinking purposes, are the dejecta and urine of human beings, such as are commonly found in the sewerage systems of cities and towns.

2009 CROSS-EXAMINATION by General Hamlin:

Made seven anaylses of the waters of the Mississippi river above Grafton, between the dates of October 16 and November 26, 1901. I received those samples at my laboratory in Brooklyn, New York. A number of years ago I made certain physical tests of the water of the Mississippi at Minneapolis. I ordinarily include under the general head of water analyses,
2010 such physical tests as that of the determination of color and turbidity. Such physical tests I made at Minneapolis some three or four years ago. I made no test for sediment ammonia, chlorines or organic matter, at that time excepting as the organic matter may be included in the color of the water. Nor for nitrates or nitrites or total solids.

2011 I received seven samples from the Illinois river at Grafton between the dates of October 16 and November 26, 1901, from one or more collectors working under the direction of Dr. Ravold. The samples were received in glass bottles which had cork stoppers and these bottles were sealed when received. I do not make any chemical analysis of those waters. Nor bacteriological examination.

2012 Those were all of the samples immediately above Grafton that I ever personally examined. And the ones that I have testified that I received above Grafton on the Mississippi, are the only ones that I have personally examined. I received some samples further up the Illinois river at Beardstown in the month of November, 1901, sent to me by one or more collectors who worked under the direction of Dr. Ravold.

Q. Didn't you expect at that time to be a witness in this case?

A. I didn't consider the matter at that time.

2013 I don't remember just when I knew that I would be called as a witness

I received five samples between October 16 and Novem- 21, 1901, from sample collectors who worked under the direction of Dr. Ravold, and who collected the samples at Fort Bellefontaine. I did not make any chemical analysis of those samples, nor bacteriological examination. I regard myself and am regarded in my judgment, as an authority on the chemical analysis of waters and the bacteriological examination of waters. The next samples I received from the Missouri river were those which were collected by Prof. Van Ornum on April 12, 1903, the present year. I received three samples.

2014 They were all taken at a depth of ten feet. I did not make any chemical or bacteriological examination of these samples. I received the samples already mentioned (from the Mississippi river above the mouth of the Missouri) and in addition 8 samples collected in a cross-section known as section M and which were collected by Prof. Van Ornum on Apr. 10, 1903. Prof. Van Ornum is professor of civil engineering in the Washington University of this city. I did not make any chemical or bacteriological examination of these waters. That covers all the samples that I have ever received from that point. I received six samples of water from the Mississippi river at Alton, Illinois, which were collected between October 16 and November 21, 1901, and also 12 samples of the water of

2015 the Mississippi river above Alton, collected on November 12, 1901. I did not make any chemical analyses or bacteriological examination of those samples. I received seven samples of Mississippi river water at the Illinois shore, opposite the Chain of Rocks, which were collected between October 15 and November 29, 1901. Also 11 samples from Mississippi river just above the Chain of Rocks, collected on November 10, 1901; also 7 samples from Mississippi river at intake, collected between October 15 and November 29, 1901. Also 24 samples from Mississippi river at cross-section which has been described as series C, just below the mouth of the Missouri river, which samples were collected by Prof. Van Ornum, on April 12, 1903. Also 33 samples from cross-section of the Mississippi river which has been described as series I, just above the intake, collected by Prof. Van Ornum on April 10, 1903. Those are all the samples. Cross-section I, I think, is about a quarter of a mile above the intake.

2016 Now these samples that I have mentioned, I did not make any chemical analysis or bacteriological examination of these samples. That is all the samples I received from the Mississippi or Missouri river, but I received other samples from the Illinois river. I received 6 samples from the Illinois river at a point 3 miles above Peoria, which were collected between October 16 and November 21, 1901, and which were sent to me by collectors who worked under the direction of Dr. Ravold. I did not make any chemical analysis or bacteriological examination of these samples. I received no other samples in any of the three rivers named, the Illinois, Missouri and Mississippi.

2017 I made no chemical analysis or bacteriological examination of the samples which I received from the tributaries of the Illinois river. I received 6 samples from the Chicago Drainage canal at the Bear Trap dam at Lockport, which were collected between October 17 and November 26, 1901. I did not make any chemical analysis or bacteriological examination of those samples. I received 4 samples which were marked Paulina street and which are included in this sheet marked Chicago Drainage canal, but I understood that these were collected from the Chicago river just before it enters the Chicago Drainage canal. These 4 samples were collected between November 8 and November 30, 1901. I received 5 samples from the Lake View crib between November 4 and November 22, 1901;

2018 3 from Carter Harrison crib between November 6 and November 15, 1901, and 2 from the 4 mile crib on November 20 and November 27, respectively, 1901. I did not make chemical analyses or bacteriological examinations of any of the samples mentioned. I made microscopical examinations of all of the samples mentioned, except those samples which were collected by Prof. Van Ornum. It does not include the 3 samples collected in the Missouri river on April 12, 1903. I didn't make chemical examinations of these samples or bacteriological examinations because I wasn't asked to do so. I could have made these examinations very easily. In my direct examination I stated that there were two microscopic organisms, vege-

2019 table plants, if you choose, synedra and tabellaria, which were especially characteristic of Lake Michigan water, but not of the waters of the Missouri or the Mississippi river above Grafton, or the tributaries of the Illinois river. I do not mean that these two do not exist in the waters of the Mississippi above Grafton. They might be found, as far as I know, in the Mississippi river above the mouth of the Illinois. I do not mean to say that they cannot be found or do not exist in the waters of the Missouri river. I do not mean to be understood as saying that they do not exist nor cannot be found, in the tributaries of the Illinois. These micro-organisms are usually found in the waters of lakes, ponds or reservoirs. I have no personal knowledge of how many lakes are situated on the Illinois river between Lockport and Grafton or whether or not there are any lakes or ponds that connect with the Mississippi river above Grafton.

Q. If there were lakes on the Illinois river between

2020 Lockport and Grafton that connect with the Illinois river, you would expect to find those micro-organisms, wouldn't you?

A. They might be found there.

Q. Well, wouldn't it be reasonable to suppose that they would be found there?

A. At times, yes, sir. And the same is true of the Missouri river and of the Mississippi river, under the same conditions. I never made any examinations of the waters of the Mississippi river below St. Louis. Never examined it at New Orleans to my recollection. I have seen the waterworks plant at Chain of Rocks, I have seen the pumping station at Baden; I have ridden along the conduit connecting the two. I have seen from the train the settling basins at Bissell's point.

2021 There are four settling basins at Bissell's point and six at the Chain of Rocks. That would make 10 all together counting each particular tank as a basin. Settling basins are used to get rid of the mud and to get rid of the suspended matter in the water also. It makes the water clearer and freer from suspended matter. It purifies the water to some extent by the removal of matter in suspension.

I consider the principal elements in the purification of water the removal of those substances which would render water impure.

Q. Has dilution anything to do with it?

A. If the water is diluted with another water which is purer than it is, it makes that first water purer. Sedimentation ordinarily makes the water purer. Dilution and sedimentation are regarded by scientists and sanitarians as two important elements in the purification of water.

2022 I wouldn't say they are regarded as the principal elements. In certain cases they are regarded as important elements. Settling basins are used in cities in cases where the original water contains large amounts of suspended matter which would settle out during the process of sedimentation. Natural water is any water found in nature. When I was asked some questions yesterday regarding sewage being discharged into natural water I meant natural water in that sense. That is the esnse in which I intended. That is the sense in which I have used the term during my entire examination by the complainant.

2023 I didn't prepare all the expert questions which were asked me yesterday. In some of them I assisted. I don't think I repeated any of them myself absolutely, or any one entire question. In my testimony yesterday in regard to chlorine, I used an average figure taken from the sheets of complainant's exhibit 1 for identification, which gave the chlorine in parts per million. I took the average, found in the Mississippi river above Grafton; in the Illinois river above Grafton and at five points in the cross-section of the Mississippi river at Alton and Hartford.

2024 I used that for the purpose of showing the mixture of the waters of the Illinois and the Mississippi. I didn't adopt the same plan of using the solids instead of the chlorines because there were no determinations of the total solids on those sheets at the five points in the two cross-sections at Alton and Hartford.

2025 Q. You stated yesterday, I think, to Mr. Jeffries, that the best test, that is the most reliable test, is the test made with solids?

A. I consider it to be such for the particular case which is being discussed, I wouldn't lay that down as a universal proposition.

2026 I believe that a mixing of the Illinois river with the waters of the Mississippi was evident at Alton.

The banks of the river from there to Grafton, from my recollection of the charts, I believe to be very nearly parallel with each other and very nearly in a straight line, barring slight
irregularities. My recollection is that there are no im-
2027 portant curves. I think that the Illinois river water
mixes with the water of the Mississippi by the time it reaches Alton, to some extent. That I understand to be about 15 miles away from where the rivers unite. I think it is about 6 miles from the mouth of the Missouri river to the St. Louis intake.

Q. In your examination you stated: "From my general knowledge of the subject of rivers and the effect of curves on the currents of these rivers, it is my opinion that this curve which I have described (referring to a curve on the map or chart which you had in front of you) in the Mississippi river, between the mouth of the Missouri river and the intake of the St. Louis waterworks, would tend to allow or would increase or would be favorable to the mixture of the waters which come down the Mississippi river and the Missouri river." Now which one of those statements do you wish to adopt, "Would tend to allow, or would increase, or would be favorable?"

A. I don't think they mean the same, but I think they are all applicable. I wish to stand by all of them. I should say the mixture I speak of would take place most rapidly in that part of the curve where the central thread of the main channel crosses from the position near the left bank to a position near the right bank.

2028 That position or place is 2½ miles below the southern point of the mouth of the Missouri river.

2029 In the statements of the population made by me in my examination in chief, I did not state the total population of the watershed of the Illinois river.

2030 It is not true that all authors use the amount of urban population and the amount of rural population instead of the population of cities which have more than 4,000 inhabitants, as the population upon which they base their research. I think that where the pollution of a stream is involved, that the rural population is an element to be considered on the question of the discharge of sewage into that stream. I do not know what the rural population of the Illinois watershed is from my recollection. I find from the report of Jacob A. Harman, included in a report of the Illinois State Board of Health, on Sanitary Investigations of the Illinois river, 1901, on page 119, that in the year 1900, it was 893,723. That does not include Chicago but only the natural drainage of the Illinois river, and what he has called the rural population.

2031 I find in the same report and on the same page that the urban population for the same region for 1900 was 617,664.

Q. I will ask you if exclusive of the Chicago river and the I. & M. canal and the Drainage canal, if there are not about fifty creeks, rivers and tributaries to the Illinois river having their watershed drain into the Illinois river, making about 25,000 miles of creek, river and tributary draining portions of Indiana, Wisconsin, and a large part of Illinois, into the Illinois, which empties into the Mississippi river near Grafton?

A. I think that statement is approximately correct. But I find on page 120 of Mr. Harman's report that the sum of the areas of the watershed of the Illinois equals 27,814 square miles; and a memorandum from the 11th U. S. Census which states it to be 29,013 square miles and another from the Chief of the Weather Bureau from 1896 to 1897 which states it to be 29,150 square miles.

2032 I have no knowledge of the lineal number of miles of river or creeks draining into the Illinois river. All I know about the rural population upon the watershed of the Illinois river is what I get from this report of Mr. Harman's, he giving it at 893,723. The report of Mr. Harman I refer to does not undertake to give the urban and rural population of all the tributaries of the Illinois river, outside of the Chicago river, Illinois & Michigan canal and Drainage canal.

2035 It is impossible for me to say how much sewage is discharged into the Illinois river and its tributaries outside of the I. & M. canal, the Drainage canal and the Chicago

2036 river. I have no means of telling with any degree of certainty the amount of sewage discharged into the Illinois river exclusive of the Chicago river, the I. & M. canal and the Drainage district.

2038 In so far as the question of distance alone, is concerned, a typhoid fever bacillus would reach the intake of the St. Louis waterworks from St. Charles, Mo., or from Alton, Ill., more easily than a typhoid bacillus of equal vitality introduced

at a distance of 350 miles from the intake. But whether a typhoid bacillus discharged at St. Charles or at Alton would actually reach the intake of the St. Louis waterworks more easily than a typhoid bacillus of similar vitality, discharged at a distance of 350 miles from the intake, would depend among other things, upon the degree of mixing of the waters into which the bacilli were discharged, before they reached the intake, and
to some extent, perhaps, upon the character of the water
2039 into which the bacillus which was introduced at a distance of 350 miles from the intake, was introduced. And it would depend still further upon the velocities of the streams
into which the bacilli were discharged at the three points
2040 mentioned. If it depended on velocity, the one nearest
the intake would reach the intake first provided the velocities of the streams were such that the one which was nearest the intake got the shortest time of transit. Alton is nearer the intake than a point 350 miles away, in so far as that flow is concerned, as I understand it.

Q. Do you want to be understood that a typhoid bacillus with equal vitality at Alton and starting on his journey to the intake, with one of equal vitality 350 miles away, that one would be as liable to reach the intake as the other, and still maintain their vitality?

2041 If by vitality you mean the ability to resist external conditions, that would depend upon the relative character of the water into which the bacillus was introduced at Alton, and the water into which the bacillus was introduced at a distance of 350 miles, and the time required for the bacillus to travel from Alton to the intake, as compared with the time required for the bacillus to travel from a point 350 miles away to the intake of the waterworks.

From memorandum that I have read, according to the 11th Census of the U. S., the drainage area of the Missouri river was about 527,000 square miles and according to report of Chief of Weather Bureau for 1896 and 1897, was about 527,150 square miles; the drainage area of the Mississippi river above Grafton according to 11th U. S. Census was about 143,512 square miles and according to report of Chief of Weather Bureau it was 126,750 square miles, while the drainage area of the Illinois river I have already given. Making a total for the three watersheds of the three rivers mentioned, and excluding the I. & M. canal and Drainage canal, of 699,525 square miles according to the U. S. Census and 693,050 according to the Chief of Weather Bureau.

2042 If, by urban population we include the population only of those towns and villages and cities which contain more than 4,000 inhabitants, I find on page 27 of the report on the water supply of St. Louis by the Commission of Hydraulic Engineers, dated 1902, that the aggregate urban population on the three watersheds mentioned in the last question was, according to the U. S. Census of 1900, 2,694,738. I do not know what the rural population is.

Q. I will get you to state if it is not a fact that in this area of these three rivers, that you have mentioned, that is within these drainage basins, exclusive of the Chicago river, the I. & M. canal and the Drainage district, if the population according to the United States Census was over 12,000,000?

A. I don't know as I haven't made any estimate of such a population.

2045 If we assume there are 12,000,000 inhabitants living upon the watershed of the Missouri river and the Mississippi river above Grafton, and the Illinois above Grafton, exclusive of the population living within the Chicago Sanitary District, and if we assume that there are living within the Chicago Sanitary District 1,639,456 inhabitants, and if we assume that the amount of sewage from each individual is the same as the amount of sewage from every other individual upon the three watershds mentioned and within the sanitary district, and if we assume further that all the sewage from all these individuals mentioned as living upon the three watersheds, and within the Sanitary District empties into the streams mentioned, the amount of sewage contributed by the inhabitants of the sanitary district of Chicago would be about 13.6 per cent of the amount of sewage contributed by the 12,000,000 population dwelling upon the three watersheds mentioned, exclusive of the Sanitary District.

2047 According to the authenticated cases of the contamination of water that has produced typhoid fever, to the best of my recollection and in the absence of my notes, it is my opinion that the distance from the point or place where typhoid fever was contracted from the point of contamination, has been *as great at times as 50 or 60 miles.*

I should say that the majority of the well recognized epidemics caused by water borne typhoid fever bacillus were due to infection less than 30 miles distant.

2051 The best way to determine the presence of sewage in water is to actually find out whether or not sewage enters the water.

Q. In the absence of that information can water be taken from a river and by any process known to science, can it be determined whether that water is sewage polluted or not?

A. Some water can be and some water cannot be. If water is much polluted with sewage that fact can be ascertained by scientific methods; if it is but very slightly polluted with sewage, it cannot always be determined by scientific methods. I have not a definite idea as to what degree of pollution I denominate much polluted.

2055 Q. Then, in order to ascertain the presence of sewage in water of the character that we have been talking about,, with these elements eliminated, is it necessary to make a chemical analysis of the sewage before it enters that water, in order to ascertain the proportion of the sewage to the water into which it enters, in order to ascertain its presence?

A. In order to ascertain the proportion of the particular sewage mentioned, it would be necessary to make some sort of an analysis. In the absence of any analysis having been made of the sewage before it enters the water it might be possible to ascertain its presence in the water into which it empties but not its exact proportion.

2056 Q. Do you know the character of the waters of Lake Michigan when freed from any sewage pollution from Chicago?

A. Only from analyses of such portions of Lake Michigan as are used for the water supply of Chicago. I couldn't state definitely whether that is free from sewage contamination or not. I am not able to state from my knowledge of the
2057 sewage of Chicago before it commingles with the waters of Lake Michigan at what proportion of water to sewage I would be able to ascertain the presence of sewage in that water.

Q. Your experience as a scientist has not enabled you to make that kind of a determination, has it?

A. It has not enabled me to determine that point exactly. I do not know of any scientist of established standing or admitted standing that has been really able to solve it.

Q. Then the line between much polluted water and slightly polluted water has never been scientifically defined as to the ratio of sewage to water, or dilution, has it?

A. It is my opinion that it has not been truly defined, and that it cannot be truly defined.

If a scientist did not know that the sewage entered the water, and if he didn't know the character of the water before the sewage entered it, the question of whether he could determine the probable presence of sewage in that water, would depend in part, upon the original character of the water and the character of the results shown by his analysis.

Q. If he didn't know the character of the water into which the sewage entered, or the character of the sewage that entered the water, in fact didn't know that any sewage entered the water at all, what would have to be the results of the analyses in order to demonstrate the presence of sewage in the water?

A. I should be unable to state in definite terms.

Q. Do you know?

A. Not in definite terms, no, sir.

2058 If I didn't know the character of the water originally or the character of the sewage; if I obtained from my analysis results which approached those in character which would ordinarily be obtained by the analysis of sewage, I should be able to form a fairly reliable opinion as to the presence of sewage in the water. I should compare the qualities which have been already enumerated, namely, the amount of organic matter as shown by albuminoid ammonia, the character of the organic matter as indicated by the free ammonia, the nitrites and nitrates; the amount of total solid matter, the matter in suspension, the chlorine, the hardness, the prevalence of certain particular species of bacteria, such for example, as the bacillus coli; the number of bacteria, the color, the presence of certain microscopic organisms, etc.

2059 There is no one element to which I should attach special prominence. Suppose some of these elements were absent, I might be able to conclude the presence of sewage pollution, but my judgment would be to that extent, or to the existence of the pollution, less reliable. Albuminoid ammonia in water serves as a measure of the amount of undecomposed organic matter present, but taken by itself, it cannot be used to determine the amount of sewage pollution present.

2060 There is no such substance as albuminoid ammonia. It is simply a form of expression for describing the amount of organic matter present. It is a form of expression for the substance and is not the name of the substance itself.

Q. Chemistry is an exact science, isn't it?

A. Fairly so.

2061 If the water is said to contain free ammonia, we meant that the water contains ammonium compounds which are such as upon boiling the water the ammonia will be driven off in such a way that its amount can be determined. Nitrites are both a name for a substance and a substance. Nitrates are also a substance which may exist in water.

2062 You can get the nitrogen of free ammonia as the term is used in water analysis, from the nitrites and nitrates. The substance for which the term albuminoid ammonia stands, may be derived either from animal or vegetable matter. In fact, it may be animal or vegetable matter. When I find the presence of albuminoid ammonia in water the science of chemistry does not enable me to ascertain whether that albuminoid ammonia comes from animal or vegetable origin.

2063 From any methods of chemical analysis with which I am familiar, it is impossible to tell whether the substance represented by the term albuminoid ammonia, is derived from animal or vegetable matter. The origin of the free ammonia which may be present, whether from vegetable or animal matter, cannot be definitely determined, although if the amount of free ammonia is high compared to the amount of albuminoid ammonia found, there is, to some extent, more reason to expect that it comes from animal matter, using the terms free ammonia as standing for the substances. I should say that that fact rises to the dignity of a scientific demonstration.

2064 Now that which is true of free ammonia is true of nitrites and nitrates, is it not, as to the origin, whether animal or vegetable?

A. Not in the same sense, because nitrates may come from substances of mineral character. It is a fact that the substances which you describe as free ammonia, that the nitrogen of that substance may become changed to nitrites, and afterwards to nitrates under the influence of certain bacteria.

2065 If you found nitrates in the water analysis, these nitrates may come not only from animal and vegetable, but also from mineral origin. When they come from mineral origin it does not come from sewage unless the sewage contains minerals from which they came. Sewage contains mineral matter besides chlorine. If these nitrates come from mineral, I couldn't say definitely that they came from mineral sewage or without knowing whether any of the sewage entered the water, or whether the water in any way came into contact with minerals which would give up nitrates. Speaking popularly, minerals do not come from vegetables, but in so far as nitrates represent mineral matter, these might be derived under the action of bacteria, from vegetable matter.

2066 If nitrates are found in the chemical analyses of water, their presence there does not indicate from what source they have their origin—whether vegetable, animal or mineral, simply because they are found there. The hardness of water is an attribute which is derived chiefly from mineral origin. It might be derived from sewage pollution to some extent when the sewage is from the fecal and urinal discharge of man.

Q. To what extent would you consider it?

A. I could not express that in definite terms, but I might say that would be a smaller fact to be considered than most of the other elements which I have mentioned. Of itself it would not decide sewage pollution.

2068 Q. Now, from the table and analyses that you have before you, (Complainant's exhibit 1 for identification) are you able to tell whether that sample of water was sewage polluted or not, or whether those elements are derived from animal or vegetable origin?

A. I am not able to tell either of those things from these figures as I find them right here, considering nothing else, than these figures.

2069 What other element would you consider in connection with those analyses in order to determine whether the chlorine, albuminoid ammonia, free ammonia, nitrites and nitrates were derived from animal or vegetable origin, as indicated in those tables marked Complainant's Exhibit 1 for identification?

A. I should want to have more information—more practical information in regard to the source of this sample and the place from which it was derived. That table indicates that sample was taken at Fort Bellefontaine, in the Missouri river.

That gives the locality of the sample, as to place and the river from whence it was taken. I should like also to know the character of the watershed from which this sample of water was derived, with reference to the existing pollutions. I think the analysis is of such a character that it would be difficult to tell from the analysis itself, whether or not this water were sewage polluted without knowing the character of the watershed. Assuming that the sewage of Kansas City, Kansas, and the sewage of Kansas City, Missouri, and the sewage from slaughter houses and cattle sheds located at those two places, emptied into the Missouri river about 400 miles above this point, those facts would indicate that this water might perhaps be sewage polluted, except in so far as the effects of the pollution may not have been interferred with by processes of sedimentation, etc., between the point of pollution and the
2070 point where this sample was collected. I should have to balance a number of different conditions in order to arrive at such a result.

2071 Q. Do you consider the water of the Missouri river above Kansas City a sewage polluted water?

A. In so far as the sewage of the cities dwelling upon the watershed of the river above that point enters the river, I should consider it as a sewage polluted river. Whether suitable for drinking purposes I am unable to state from the facts which I have at hand.

2072 I stated that whether the sewage of Kansas City reached Fort Bellefontaine in quantities sufficient to be detected, or have any effect upon the water when used for drinking purposes, depended upon dilution, sedimentation, the action of bacteria—I would say the possible action of bacteria and microscopic organisms or other such natural agencies and I understand you are barring out any artificial actions which might be introduced. The amount of dilution necessary to meet the requirements of my answer would depend upon the character and the amount of the sewage and also perhaps upon the relative effect of some of the other agencies mentioned, including for example, the time of transit of the water from the one place to the other. I don't know the exact amounts of dilution because I don't know the volume of the sewage and I don't know the volume of the stream at that point.

2075 The presence of the bacilli coli communis I could not state definite that it indicates sewage origin. It is believed by many scientists today that this organism may be found in waters where pollution may be remote. I hold that if this organism is constantly present, or is very often present in a water, and if this organism is present in such numbers that we can readily determine its presence by analyzing one cubic centimeter or less of the water, it is probable that this is an indication of contamination by fecal matter. I do not believe that the test is an absolute test, but I consider it is a valuable one to be interpreted in connection with the rest of the analysis.

2076 The bacilli coli communis is found most commonly in the intestines of man and certain animals, for example, the cow, horse, pig and I think birds and speaking generally, in warm blooded animals.

It has been my experience that the intestines of fish do not ordinarily contain bacillus, and that if this bacillus is found there, it is a case where the bacillus has been derived from the water, and I base my judgment upon considerable personal work which I have done in that direction. I would disregard its presence in the intestines of fish in the Missouri river so far as any interpretation were made from the presence of the coli communis in the water.

2078 Q. What organisms—what micro organisms found in water demonstrate sewage pollution from the fecal discharge of man?

A. I don't know of any that absolutely demonstrate its presence, but there are certain microscopic organisms or microorganisms which are so often associated with sewage that in a very general way they do serve as an index of the presence of sewage, but I wish to be understood as saying that they indicate it only in a general way. I could not assert that a stream was sewage polluted because these organisms were found in the water, barring all other considerations. There are none of the elements which you have mentioned taken singly, that would demonstrate their origin to come from the fecal discharge or the urine discharge of man, if found in waters. And even when taken collectively, they are not able to demonstrate their origin as coming from the urine or feces of man, but taken collectively and making comparisons with what we know of their character and amount of sewage, we are sometimes able to judge as to whether or not a water may be polluted with sewage which presumably contains the dejecta and urine of man. I wouldn't call that a straight scientific demonstration, but I would consider it what you may call a reasonably correct judgment That judgment is liable to be mistaken like all human judgments.

2081 I don't know definitely how long the bacillus of typhoid will live in sewage contaminated water. I don't know of any scientist who actually knows. I know the bacillus of typhoid will live in sewage polluted water, but scientists have made laboratory experiments to determine that fact and they have arrived at certain conclusions. I do not consider conditions in the laboratory where experiments have been made, similar to conditions that exist in a running stream, sewage polluted.

2082 I know of people who have claimed to have discovered the germ of typhoid in running waters, but I am unable to state whether they actually did discover that germ in running waters or not.

2083 I don't see how it is possible in the present state of bacteriology for reliable experiments to be made as to the rate typhoid bacillus dies out in running waters.

2085 I believe that the best scientific information which we have leaves us to suppose that after leaving the human system, typhoid bacilli do not ordinarily multiply in the water.

Q. Would the presence of lakes in the river act as settling basins for the purification of the sewage discharged from the Drainage canal at Lockport?

A. If such lakes were present on the Illinois river, and if in such lakes the water therein should become more quiescent than in that of other portions of the stream, the suspended matter of the sewage—the suspended portions of the sewage might tend to settle more rapidly than in the swifter portions of the stream. Purification of the water which contained the sewage would depend in part upon what happened to the suspended matter after it had settled, and whether or not the suspended matter was afterwards carried into the stream again, to Grafton.

From what I have learned from reading various reports which describe the conditions of the Illinois river between Lockport and Grafton, it is my opinion that at times such sedimentation may take place. That is at times when the
2086 velocity of the water in the stream was low. Flood conditions would add to the dilution. They would increase the dilution of the sewage.

2087 There are four dams in the Illinois river.

They are there for the purpose of assisting navigation by raising the water and backing it up stream. Now when the water in the Illinois river is at normal and is backed up by these dams, would not the backing of the water up above the dams act as settling basins?

A. If in this water above the dams the velocities were reduced to such a degree that sedimentation of suspended matter could take place.

2088 Q. What is your individual judgment upon the subject as to the speed of a current that would be necessary in order to permit sedimentation?

A. My judgment is that if the velocity is reduced say from a quarter to one-third, or perhaps to a half a foot per second, sedimentation of suspended matter of a certain character might occur. If the suspended matter were coarser, it would settle with greater velocities. I can imagine suspended matter so fine that it would not settle even at those velocities.

Q. Suppose that the current was a mile in two hours, would sedimentation take place?

A. I think it would, sedimentation of substances of a certain character.

2089 Those four dams in the Illinois river, I think they would allow sedimentation to take place under more favorable conditions than if they were not there to just the extent to which they reduced the velocity of the stream. Of course we understand that the laws governing sedimentation of suspended matter would apply to the Illinois river the same as they would apply to other streams, and I know from reports that sedimentation actually is said to take place in the Illinois river at certain places. I think that a velocity of one mile in two hours would allow sedimentation of a certain size or kind of suspended matter to take place. Under the conditions which exist, it is my judgment that the proportions of the sewage, of all parts of the sewage of the city of Chicago, would not be eliminated by the time that it reached Peoria. I am unable to state definitely what part would be.

2090 I said parts of the sewage, and when I said parts I did not mean a half, or a quarter or an eighth or sixteenth. I mean parts of the sewage, understanding that sewage is not a single substance, but is composed of various ingredients. If we take chlorine, for instance, which is a constituent of sewage, that chlorine would not be affected by sedimentation, for instance, but practically by dilution, and to that extent the sewage of Chicago would not be eliminated by the time it reached Peoria, but simply reduced in amount by the dilution it might receive. From what I know of the existing conditions on the watershed of the Missouri river and from the fact that there are certain salt deposits, and from analysis which I have seen showing the indication of such salt deposits, of the effect of such salt deposits on the water of the Kaw river, it is my opinion that the chlorine in the Missouri river, in its low reaches, cannot be used as an index of pollution, although part of it may be derived from sewage pollution, because the effect of the chlorine from the salt deposits, would simply mask any chlorine from sewage pollution, and in that particular case the chlorine could not be used to determine whether or not the water was sewage polluted.

2091 Q. Is it your opinion, and I believe you stated that the increase in typhoid in the city of St. Louis, is due to the sewage from the Drainage canal, from 1900, 1901 and 1902?

A. I think that I stated that under certain conditions which were assumed, the most probable cause of the increased typhoid in the city of St. Louis during that period was due to the sewage of Chicago, meaning by that that was the easiest explanation of the increase under the conditions which were assumed.

Q. Does an easy explanation always explain, Mr. Whipple?

A. It doesn't always explain.

2095 You cannot state as an established fact that the opening of the canal at Lockport is the cause of the increase in typhoid in St. Louis, can you?

A. I cannot state it as an established fact absolutely, and conclusively proved.

2096 I don't know that the sewage of Peoria purifies itself in 25 or 50 miles. If you mean by purification, the fact that the water into which the sewage of Peoria is discharged because free from all the constitnents of that sewage, if you put the time within 25 or 50 miles, or if you mean by purification the fact that the water into which the sewage of Peoria is discharged, becomes free from all the constituents of that sewage, I should say that it did not.

Q. Would it purify itself by the time it got to the St. Louis intake?

A. If you mean by purification of the sewage the fact that all of the elements of the sewage were absolutely removed from the water I should say that it did not, but in connection

with both of these answers, I wish it to be understood that the
factors of dilution, etc., must be taken into consideration.
Chlorine in water is not injurious to health unless you get an
excessive quantity of it and it would probably be impossible
to get enough to injure one as I understand your question. In
order to make water dangerous to the public health, it must
contain something which would affect the human system, and
that something would ordinarily be a pathogenic germ, rather
than any form of poison, or anything of that sort. If
2097 you wanted to know the character of the microscopic
organisms in the water for the entire year and the
changes which might take place in the number of microscopic
organisms present at different seasons, the samples should be
taken at different seasons of the year, and the more frequently
these samples were taken the better would be our knowledge in
regard to the general character of the water with respect to
microscopic organisms. Take one set of samples in a cross-section
of the Illinois river and examine them microscopically,
and we would learn the condition of the water at the point
where the samples were collected at that time.
2098 That determination might not apply to the conditions of
the river a month previous or a month subsequent. One
set of samples taken at a selected time would give reliable information
as to the character of the water of that stream at
that time at the point where the sample was taken.

Q. And at no other time, or at no other point?

A. No, sir, so far as those samples alone were concerned,
and in the absence of any one from which we know that those
waters remained constant in character through a period of
time.
2100 In making up an opinion as to the conditions of these
rivers, I have assumed that the results which I have seen
as tabulated or published, were correct.
2101 I do not consider that there is a well defined standard
regarding what I may term the safety of water with respect
to its use for drinking purposes, excepting that of the

absence of substances which might render the water unsafe. It is my opinion that it is practically unknown subject as to whether or not the presence of microscopic organisms would render a water which once unsafe, safer for use than if they were not present. So that the presence of a greater or less quantity of any kind of micro-organisms such as I have named, is not indicative that the water is undergoing a process of purification.

2102 Any one of these groups, (diatomaceae, chlorophyceae and protozoa) might encounter conditions which might exterminate them so far as their life were concerned, but I have already testified that the cell walls of the diatomes are practically indestructible in water. Diatomes are found in all surface waters, to a more or less extent.

2103 The synedra pulchella variety sub prolongata is more commonly found in ponds—in the waters of ponds and lakes than in the waters of streams, except in so far as those streams might be fed by lakes which contain them. I mean the natural habitat of the organism is in ponds and lakes. That is also true of some species of tabellaria. If the variety of synedra which I have mentioned, and the tabellaria could be required to pass through twenty miles of what has been called pure sewage, I think it might survive the journey.

2104 Assuming that the Illinois river has upon both banks from Joliet to Grafton, or from La Salle to Grafton, large numbers of ponds and lakes, many of which are fed by springs, over-flowing in time of high water, and acting as feeders to the Illinois river in time of low water, having their low water outlet into the Illinois river, the synedra and the tabellaria of which I speak exist there.

2105 If we have a certain volume of water contributed by the tributaries of the Illinois river, and the assumed lakes which are assumed to contain a certain number of these organisms, and if we have a greater volume of water from the Chicago Drainage canal which contains per cubic centimeter an equal

number of these organisms; then if we assume a thorough mixing
of the waters, it would be my judgment that the organisms
found in the resulting water would be more likely to come from
Lake Michigan than from the other sources named—it would be
my judgment that these organisms would come from both
sources, but that more of them would come from the water which
was greatest in volume, provided that the two waters contained
an equal number per cubic centimeter. All other considerations
2106 being equal. I don't think the fact that the supposed
organisms traveled through 22 or 24 miles of sewage,
of any consequence, for the reason that in the examinations
that I have made I have not attempted to differentiate
between a live synedra and a synedra not capable of developing.
2109 I do not know that one thousand million
bacillus prodigiosus could be concentrated in one cubic
centimeter and exist for two days alive. A bacillus may be
carried by water from one point to another provided nothing
happens to it on the passage. I suppose it might be taken from
the river by pump and through along the decks of a steamer
traveling up the river, in the process of washing decks, and go
out into the river again, five or ten miles above where it was
taken from. If conditions were favorable, a bacillus might be
taken in a portion of water and put in a boat and carried up
stream and then put down in the water again.

2110 I think that the bacillus—speaking in general—might,
under certain conditions, become attached to a duck, for
example, the duck might travel up stream and the bacillus
might get away from the duck and go into the water. I think
it might be taken up by a duck or through a pump and be used
for the purpose of washing the decks of a boat and returned to
the water again alive, three or four miles or ten miles from
where it was taken out. So far my knowledge goes, that principle
would apply as well to prodigiosus as to any other bacillus.
The fact that the bacillus prodigiosus—one colony of them
—was found three miles up-stream from the place at which it

was put into the river, would simply show that the water at that point, at that time contained this bacillus.

2111 It is my opinion that if the bacillus were taken out from the place where it was put in and carried up by boat three miles and put into the water—it would be there. I think it would bear the transportation probably, under the circumstances which you have mentioned.

Q. Suppose bacilli, naturally inhabitants of running waters which are turbid to some extent, should be removed from their natural place of abode, developed by special culture, put in bottles of sterilized water, and hung out in the sun, would that be a fair means of determining how long they live in their natural waters?

A. I don't think it would enable us to tell how long they would live in their natural waters, no, sir.

2112 An experiment of that kind does not enable us to give a definite opinion as to the life of any particular bacillus in its natural situation.

2113 Q. Taking into consideration all that you know of the physical conditions surrounding the Drainage canal, Illinois river, the Mississippi river and the intake, and the character of the prodigiosus bacillus, and assuming that some bacillus were put in near the mouth of the Illinois river in August, 1900, and in November, 1901, 107 barrels of them were put in near Lockport, and that they were afterwards found at the intake and in taps of the city waterworks here, could you tell, with any kind of certainty, to which dose of the bacillus put in those waters, those found were to be attributed?

A. It is my judgment that if those came from either the one dose or the other, that they came from the second dose rather than the first.

2115 If you consider the question of percentage mixture, I would say that the percentage of mixture of the two waters would not be the same at all times, of Mississippi and Missouri water.

2116 As a rule, if we consider a certain point below the point of mixture, the percentage of the waters would not be the same at all times, on account of natural variations in the flows of the two streams, and questions concerning their currents, etc., so that when it is determined that upon a certain day the percentage of the Mississippi water and the percentage of Missouri river water bear certain relative proportions to each other, that determination would not necessarily apply to any time. It would simply apply to that one time. When I testified here to percentages of volume of water of the Missouri river and the Mississippi river at the intake, based upon total solids and also upon the chlorine as to the Illinois and the Mississippi, I meant to say that the percentage of water carried a certain percentage of the solids in solution and represent relatively the volumes of the water as far as the solids represented the samples.

2117 I think if the determinations for the chlorine represent fairly the waters from which the samples are taken, that the calculations will give us the limits of accuracy governed by the sample and the determinations of the percentages of the two waters.

2119 (See pages 2118 and 2119 for method employed in determining percentage of Illinois and Mississippi river at various points.)

2120 CROSS-EXAMINATION by Judge Springer:

2121 The larger the number of samples and the more complete the examination made, the better judgment we could make of the sanitary condition of the water or the sample analyzed. Microscopic examinations of water cannot be depended upon to determine the pathogenic qualities of drinking water. So far as I know the common microscopic organisms found in water are not the cause of disease. Their presence does not definitely indicate pollution but as I have already testified, there are certain forms of microscopic organisms which are so commonly found in waters known to be polluted that to some extent their presence in water is indicative of pollution—to a ical examination does not definitely determine the nature of the organic matter in the water. Some microscopic organisms are very susceptible to changed conditions of temperature and light.

2122 In order to obtain the most accurate result, the bacteriological examination of a sample of water should be begun immediately after the time when the sample is collected, but the character of the water would, to a considerable extent, influence this fact. Water which came from the Illinois river during the months of October and November should be examined immediately after the sample was collected or within a few hours of the time of its collection.

2124 As to the samples I examined microscopically and which were examined three or four days after being taken, I would say the results would have been the same if I had examined them immediately upon being taken from the water, so far as diatomes are concerned, but perhaps not so far as some of the more delicate forms are concerned.

2125 I stated in my examination that there were two organisms which I called synedra pulchella variety sub prolongata, and tabellaria which were especially characteristic of Lake Michigan waters, but I think I stated that only with regard to the synedra pulchella variety sub prolongata, that that organism was not found anywhere else than in the water of Lake Michigan, or the waters with which Lake Michigan might have been afterwards mixed. The microscopic organisms which I found in Lake Michigan are found in all parts of the world and in great variety of climatic conditions, speaking generally. These organisms have received a great deal of attention.

Q. Are the laws governing their distribution in determining the places at which they may be found, understood at this time by scientists?

A. They are certainly not fully understood. I think we are beginning to understand something concerning these laws.

Q. May not a certain genus of the varieties to which you have referred, grow vigorously in one pond or place, and be absent from a neighboring pond where the conditions are equally as favorable for its existence?

A. Yes, so far as we know those conditions, I can recall such cases.

Q. Does it not often happen that a certain genus of the species to which you have referred may suddenly appear in a pond, lake or water in which it has never been before seen?

A. They certainly do suddenly appear in waters where apparently they have not before been seen, but just how far back observation has extended in regard to the previous history of that water, or just how far observations of a scientific character have been made concerning that water, would have to be taken into account in comparing their presence to-day with their presence on former days.

2126 An examination of a sample of the water in the Missouri river, or in the Mississippi river above Grafton taken today might show the presence of the two genera which I failed to find in the samples found in Lake Michigan.

2128 The samples of water that I examined microscopically were taken in October and November. If additional samples of water had been taken during that year in other months, at Fort Bellefontaine and in the Mississippi river above Grafton, it might be that I would have found the two genera of micro-organisms which I failed to find in the samples submitted to me from those points.

In the typhoid epidemic of Lawrence, which I mentioned, it was supposed that the bacilli travelled somewhere near 21 miles.

2129 The other case, which was that of Detroit, the distance travelled was from 50 to 60 miles. I think I have heard of greater distances, but I am unable to recall at the present moment. I mentioned the distance of 50 or 60 miles the other day, because I felt quite sure it had been carried at least that. The distance travelled is only an important factor in so far as

it affects the time required for the bacilli to travel through
water. I don't think it is any question of linear distance so
much as it is time transit. There are a great many other ele-
ments to be considered, for example, the so-called vitality of the
organisms; the rate at which they die out in water, the rapidity
of the current in which they flow; with reference to possible
sedimentation; the possible phenomena that they might settle
to the bottom of the stream and again be taken from the bottom
of the stream and carried down; the question of the tem-
2130 perature of the water might influence their vitality and
the character of the water might, to some extent. I
think it is the concensus of the opinion of scientists that such
a pathogenic germ as typhoid fever for example does not develop
in water, but on the contrary dies out.

2131 Their presence is best accounted for by considering the probable presence of the dejecta and urine of human beings which contain such bacilli so that when any of these pathogenic germs are destroyed in transitu they reduce of course the possibility of transmission of disease in proportion to the number destroyed in transitu. Scientists or authors have not ascertained by any experiments today the probable duration of pathogenic germs such as typhoid fever, in running water except by means of laboratory experiments which naturally cannot be made under the same conditions as actually exist in running waters. It is my opinion, speaking generally, that the laboratory experiment would be less favorable to their longevity than the natural conditions. (Witness is shown "Micro-organisms in Water," by Percy and G. C. Frankland, showing experiments made as to the longevity of typhoid bacillus.)

2133 From those figures I should question whether the results that he actually obtained would stand the test of the bacteriology of the present day.

2134 I considered the question of sedimentation in those expansions of the Illinois river to which references have been made and it is my opinion that under certain conditions, sedimentation of bacteria might certainly occur in those places.

2136 The greater the amount of dilution of a polluted water, the less danger there would be from drinking this water, so far as dilution alone is concerned.

2137 It is quite conceivable that the conditions in the Illinois river between the Chicago Drainage canal and Peoria (taking into consideration the Narrows) are such that the total numbers of bacteria in the Illinois river at that point, might be as low or even lower than the numbers of bacteria in the waters of Lake Michigan before it received the sewage of Chicago, but I would add to that, that when we speak of a bacteriological condition, we must consider not only the number present but also the character of those bacteria. The probability is that pathogenic germs would decrease, but whether or not they would decrease exactly in proportion to the water bacteria, is a thing which I cannot state.

2138 It is my general impression from experiments that have been made, that at most temperatures water bacteria would live longer in water than the typhoid bacilli. If we neglect all other conditions, such as sedimentation, etc., etc., and consider only the fact that typhoid bacilli do not multiply in water, while water bacteria do multiply under the conditions assumed, why then it is probable that the typhoid bacilli would not linger in water as long as the bacilli which multiplied there, but as a natural practice it would not do to neglect all such other considerations in studying a problem of that character.

2139 Q. This work by Percy and G. C. Frankland, on pages 100, 101 and 102, refers to experiments made by one of the authors, by bacteriological examination of the waters of the River Dee in Scotland, the results shown here are that near the mouth of the river the waters exhibited about the same number of micro-organisms as it did 40 miles up the river and that there were as many as four different sources of pollution entering the river and that after each one, the river reached its normal condition and came out at the end comparatively bacterially pure. In view of these facts, is it not highly probable that the waters of the Illinois river, in passing from Joliet to the Narrows, above Peoria—a distance of over 100 miles—were rendered comparatively bacterially pure, by reason of the sedimentation, oxidation and other causes tending to the purification of rivers?

(Objection by Mr. Jeffries.)

A. It is my opinion that the conditions which exist in the River Dee have not been described with sufficient completeness as to the amount of dilution, course of the stream, sedimentation, etc., to enable a fair comparison between the River Dee and the Illinois river.

2141 Assuming that there was a typhoid epidemic in 1890 in cities on the Missouri and Mississippi and that the sewage of the respective cities was emptied into the Missouri and Mississippi rivers, speaking very generally, the danger of contracting typhoid fever by drinking the water of those streams would decrease down the stream.

2142 Q. Then the danger of contamination of the lower river would be lessened in proportion as the pathogenic germs were eliminated by the sedimentation and other causes to which you have referred?

A. The danger from drinking the water in the stream further down the river is certainly lessened in proportion as typhoid fever germs are actually eliminated from the water.

(Question propounded in which the number of deaths from typhoid and population of various cities which drain their sewage in the Mississippi and Missouri rivers, is given, the number of deaths from typhoid being in each instance from 4.5 per 10,000 to 21.7, ending with New Orleans with 1.9 per 10,000.)

Q. How do you account for the fact that the death rate of New Orleans, which was 1.9 per 10,000 persons was less than it was in any of the up-stream cities to which I have referred?

A. The problem is too big a one to be solved without knowing many more conditions than anything that I have at hand at this moment, aside from these figures.

2144 I have no doubt that starting with Denver and the Missouri river and St. Paul on the Mississippi river, and continuing down the two streams, both before and after their junction, that in so far as the bacilli—typhoid fever bacilli in the sewage of those cities are concerned, there was an increasing dilution; there may have been sedimentation; there was no doubt a dying out of the typhoid fever bacilli. On the other hand, some of the bacilli which settled may have been again carried into suspension and borne a distance, possibly to be again settled; possibly to be again carried on, and I should judge from these figures, that the water which was being used by the people of New Orleans, for example, was less dangerous from the standpoint of typhoid fever, than the water which was being used by the city of Memphis, for example, assuming that there were no local conditions or no other conditions to account for the difference in the typhoid fever rate. In short, the death rate from the typhoid fever in the two cities for a certain period offers a fair index for the comparison of the danger of the two water supplies for the period, irrespective of other causes which might account for some of the cases aside from the water.

2146 I do not think it is universally recognized as a fact that the greatest pollution in streams of water is at times when the flood is greatest or the flow of water is the greatest. At times of flood or spring rains, there might be a greater amount of polluting matter washed into the streams but, on the other hand at such times the volume of water is usually large and dilution greater, so that the result might not be different from what would occur under normal conditions by the constant pollution of the stream by a sewer, for instance. I do not believe there is any practical method by which pathogenic germs can be determined in water, either chemically or bacteriologically.

2148 I believe it to be a fair statement to say that in ordinary natural running waters, there is no practical method by which the presence of the typhoid fever bacillus can be determined. I do not think it is absolutely impossible to do so, but there is no practical every-day method for doing it.

The germ might be there and you might fail to find it and it might not be there when you failed to find it.

RE-DIRECT EXAMINATION by General Crow:

I certainly believe that the liquid leaving the Chicago Drainage canal at Lockport is polluted.

2149 If we consider the liquid which leaves the Chicago Drainage canal at Lockport to be polluted sewage, and to be flowing at the rate of 300,000 cubic feet per minute, and if to that is added 40,000 cubic feet per minute of diluting water, the sum of these two amounts would be 340,000 cubic feet per minute, and of this sum about 88 per cent would be the diluted sewage. (Witness does not take into consideration the Lake Michigan water entering into the sewage.)

2150 I believe that at times the contamination of the water supply of Chicago, at the intake cribs of said city is appreciable. (Objected to by Mr. Todd and Mr. Johns.) Assuming that an epidemic of Asiatic cholera should occur in the city of Chicago, under existing conditions it is possible that the germs of that disease might find their way into the intake tower of the St. Louis waterworks, because I do not believe there are any existing artificial or natural agencies which would, at all times, insure the prevention of these germs reaching the intake.

2151 I believe I have stated that the banks of the Mississippi river from Grafton to the mouth of the Missouri are straight, barring certain sinuousities—I forget just the expression which I used. I know that the channel does change from side to side a number of times during that reach of the river, as I recall it, some five or six times, passing from a position near the right bank to a position near the left bank. As to the effect which this changing channel would have on the mixing of the water, I believe that it would tend to assist the mixing of the Illinois river water with the water of the Mississippi river, and that a greater mixture would naturally occur than if the channel formed a perfectly straight line during that reach. I stated that the Mississippi river had two sharp bends in it between the mouth of the Missouri river and the Chain of Rocks intake tower and I believe that just as these bends would tend to increase the mixing or commingling of the waters of the Mississippi river with the water of the Missouri, so it would tend also to mix the waters of the Illinois river with the waters of the Mississippi and with those of the Missouri river. Speaking as an expert, I do not think it is possible for the Illinois river water at all times to flow from Grafton to the Chain of Rocks, and by the Chain of Rocks without some of it reaching the intake tower of the St. Louis waterworks.

2152 Assuming the minimum stream flowof the Mississippi river at the Chain of Rocks is at times as low as 40,000 cubic feet per second and assuming that the flow of the Chicago Drainage canal is increased in the future from 5,000 cubic feet per second to 10,000 cubic feet per second, it is my opinion that under the increased conditions of flow there would be a material increase in the liability of infectious material to reach the intake tower of the St. Louis waterworks from the Drainage canal.

MR. TODD: I object on the ground that the facts assumed have not been proven and that this is not re-direct examination.

I should say that the conditions assumed in the last answer would tend to increase the proportion of Illinois river water which would become mixed with the water of the Mississippi. (Same objection.) (Question asked giving results of analyses of three different samples of water.) If these three samples are supposed to represent different mixtures of pure water and sewage, I should think that so far as dilution alone is concerned, sample No. 1 contained the least sewage, sample No. 2 contained more than sample No. 1 and less than No. 3 and that sample No. 3 contained the most, speaking solely with respect to dilution.

2154 On the basis of the chlorines, I would say that the relative dilution of sewage in the three samples is as to the amount of chlorine in each, which were 6 in the first sample, 16 in the second and 26 in the third, that would not be an exact ratio, but for practical purposes it would give us the desired result. If informed that the first sample represents Chicago water from the tap at 2421 Dearborn street, and that the second and third samples represent water taken from points on the Illinois river, since I was interpreting the results simply from the standpoint of a water analyst and under the assumption named in the previous question, it would make no difference where the samples came from. If water of the character of sample No. 1 has been the cause of typhoid fever, and if this sample be compared with samples Nos. 2 and 3, which, according to the analyses and the previous assumptions indicate a less degree of dilution with the sewage, it would be my opinion that there would be more chances of samples 2 and 3 causing typhoid fever than sample No. 1 so far as dilution is concerned.

2156 It is my judgment that the water of the Mississippi river below the mouth of the Illinois and above the St. Louis waterworks intake is less valuable for drinking purposes now that before the opening of the Drainage canal January 17, 1900. (Objected to for the reason that the value of the water prior to the opening of the Canal has not been proven nor witness has not shown his knowledge thereof.)

RE-CROSS EXAMINATION by Judge Johns:

Supposing that the current of a stream in its deepest part runs close to a precipitous curved bank of a river at the rate of three miles an hour when it comes to a point where the river is again straightened—or, in other words, assume a condition where there is a curve, followed by a straight stretch and where the current at the curve is near a precipitous bank, it might follow along the straight reach and on the other hand it might be deflected to some extent across the stream again. It is possible it might be either of those things—there would without doubt be a slight deflection, that would be the natural condition.

2157 I do not believe that it would keep exactly to a straight line along a straight stretch under the assumed conditions of a uniform cross-section. I have not been on the Mississippi river between the Chain of Rocks and Grafton. I derive my knowledge of the banks and curves and reaches of the Mississippi between the Chain of Rocks and Grafton from several maps, among them the Government charts and charts of the Mississippi river commission.

2158 I don't recollect the date of these maps. They were the same charts which I examined with reference to the cross-section for turbidity for my examination in chief. I don't think any of these charts were within the last ten years. I think they were made along in the 80's. I do not know whether these charts represent exactly the condition of the banks and curves of the Mississippi river in January, 1900. I understand that the banks of the Mississippi do change from time to time, sometimes rather suddenly, due to the variations in the flow of the stream—due, perhaps, to the cutting away of some of the banks, the cutting away of the bank might be caused by a change in the direction of the current or in the amount of flow.

2159 My knowledge of the probability of the waters of the Illinois reaching the intake is not derived from a personal inspection of the river, but from various maps and charts which were made from 1870 to 1880. Assuming that the volume of the Illinois river at Peoria before the opening of the canal given me, namely 40,000 cubic feet per minute, is the lowest known stage of water of the river at any time within the last 25 years, that assumption would be fair upon which to make a calculation of the percentage of dilution with reference to that particular time. I could form simply an opinion of the dilution at the time the figures were given.

2160 I know of no exact requirements of scientists as to the dilution of sewage with good water so that the water might be used with safety. I prefer the word "safety" to "potable" because the word "potable" in testimony does not convey to my mind a definite meaning. Water polluted with sewage can be diluted to such an extent that the chance of contracting disease by drinking the water is very remote.

2161 The greater the dilution the less the chance of harm, so far as the dilution goes.

Q. Assuming that the city of Chicago had for fifteen years prior to 1900, discharged into the Illinois and Michigan canal substantially the same amount of sewage that has been discharged by the Drainage canal into the Illinois river since 1900, with a dilution of only 40,000 feet per minute, would you think that that sewage had, during that fifteen years, reached the intake at St. Louis? Objection by Mr. Jeffries.)

Q. I just want to know whether if it goes into 40,000 feet of dilution in the Illinois river, it is just as likely to reach the intake as with 300,000 feet of dilution?

A. I understand that you made no comparison; I understood you to ask if it did? Q. Yes, sir.

A. And I believe that so far as dilution goes, it might.

Q. Well, if the waters of the Illinois river, to which are added 300,000 feet of water from Lake Michigan, certainly reach, in your opinion, the intake at St. Louis, why wouldn't the waters of the Illinois to which were added 40,000 feet, as certainly reach the intake at St. Louis?

A. I think that so far as dilution alone is concerned, they might as certainly reach, so far as dilution is concerned.

Q. But if for 15 years prior to 1900, substantially the same amount of sewage discharged into the Illinois river from Chicago, diluted with 40,000 feet of water as is discharged since 1900, diluted with 300,000 cubic feet of water, then the danger of disease in St. Louis from the sewage of Chicago, diluted with 40,000 feet of water, would be more than seven times as great as if diluted by 300,000 feet of water, would it not?

MR. JEFFRIES: I object to that question for the same reasons stated in my objection to the previous question.

A. In so far as dilution itself is concerned, that would practically be the case, so far as dilution itself is concerned;

dilution is a good thing. I do not know whether there ever was
any Asiatic cholera in Chicago.
2163 As to whether Chicago might have an epidemic of Asia-
tic cholera would depend wholly upon circumstances.
If our health officials in most of our cities, particularly the sea-
coast cities of this country did their duty, this country ought
not to be visited by cholera, but I cannot say and no one can say
when cholera might not occur in this country. When I say that
the pollutions in the Illinois river are sometimes appreciable
at the intake, I mean that if the Illinois river is polluted that
that pollution may reach the intake, at the Chain of
2164 Rocks, but I cannot state the extent to which it would
reach the Chain of Rocks, or when it would. I cannot
say whether it would at all times. As a general rule, typhoid
fever comes in the early fall in this hemisphere. I could not
say definitely whether the pollution in the Illinois river was ap-
preciable at the intake, in the fall of 1902. By appreciable,
I mean that it may have an effect upon the health of the people
who drink the water. I cannot say that it does, as a matter of
fact, have an effect upon the health of the people, but I believe
there is a possibility that it might.
2165 I do not know that the waters of the Missouri river have
an appreciable effect upon the character of the water at
the intake, but I believe that they may. I attribute the extra-
ordinary amount of matter in suspension in the waters of the
intake to come largely from the Missouri river. If there were
typhoid fever germs reaching the intake on a certain date from
the Missouri river, and if there were others reached the intake
from the Mississippi river and others reached it at the same time
from the Illinois river, and if these germs caused typhoid fever
in the city of St. Louis, I couldn't say exactly which one of the
three or whether all of them caused the typhoid fever, and I
couldn't tell the relative number of cases which each one caused
without knowing more about the number of germs that came
from each one. If, under the conditions supposed in a former
answer, the typhoid germs from the Missouri river traveled

forty miles, those from the Mississippi 100 miles and those from the Illinois 350 miles and supposing that the time of transmission to St. Louis was proportionate to the distance named, so far as that fact alone—disregarding everything else and disregarding the numbers and those other factors, and considering the question of time, why, those nearest might be con-
2166 sidered as having the greatest effect, but in making a true comparison, you would have to compare all factors.

2169 In regard to the questions asked me in relation to sample Nos. 1, 2, and 3, supposing sample No. 2 was taken above Peoria and represented fairly the quality of the water at that point at a given time, by the time that water reached Grafton, I should suppose that it would be changed, under existing conditions. The process of nitrification would practically have changed it to some extent. It would have changed it for the better. If sample No. 3 was taken below Peoria, the same conditions would apply to that. If after the arrival of these two conditions of water thus improved, they were added at Grafton to the Mississippi river in the proportion of 1 to 7, at the time they reach the intake, they would be changed, as far as nitrification is concerned probably.

2170 I suppose that process might keep on, in the Mississippi river to some extent. They would be changed by dilution. After the mixture of the water of the Mississippi river, the resulting water would no doubt be quite different from that in the Illinois river. I could not say from these anaylses whether either one of these samples are positively bad and unsafe for drinking purposes. I could not say whether they would produce typhoid fever or other disease.

2171 RE-CROSS EXAMINATION by Mr. Todd:

I could not say exactly what proportion of the 300,000 cubic feet of water that is passing over the Bear Trap dam at present, is sewage and what proportion is Lake Michigan water.

2173 When I stated that 88 per cent of the flow at Peoria was made up of Chicago Drainage canal water, I figured on 300,000 cubic feet from the Drainage canal and 40,000 cubic feet from the Illinois river, but I cannot tell you the exact proportions of Lake Michigan sewage in the water. In the samples known as Nos. 1, 2 and 3, I could not tell whether those samples indicate sewage pollution without regard to anything else. I should want to know the character of the water, the character of the so-called pure water with which the sewage was supposed to be mixed. I should desire to know something about the bacteria present, the abundance of bacillus coli, and the color and odor of the water may be of some assistance.

2174 I was able to make a comparison between those samples in regard to the diluted sewage contained in each, because they were assumed to be a mixture of pure water and sewage and I was simply asked to compare one with the other.

2175 Q. If three samples of water, such as you have testified to, should be presented to you and your analyses should disclose ingredients such as have been assumed to exist in these three separate samples, and your opinion was asked as to whether those samples were sewage polluted or not, what answer would you make?

A. I could not be able to tell definitely from these. I could give some idea possibly as to the relative probability, but I could not give what I would consider a definite answer from these analyses.

Q. Could you give any scientific opinion based upon these analyses alone?

A. Based upon any one of these analyses alone, without considering anything else than the figures here shown; and without knowing the source from which they came, I couldn't state definitely that these were samples of sewage pollution if I knew absolutely nothing about them aside from these figures. There is nothing in either one of those samples which would indicate that if a person took into his system water chemically similar to either one of those samples that he would contract typhoid fever. There is nothing connected with the analyses of these three samples that would indicate typhoid fever.

2176 The germ of small pox is not transmitted by water. The same is true of scarlet fever. When the assumption was made that sample No. 1 referred to would cause typhoid fever in Chicago, there was nothing in the sample indicated that such a condition would obtain. Without any assumption that these three samples were all mixtures of pure water and sewage I could not say, from samples Nos. 2 and 3 that they contained sewage. Assuming that the water at Grafton, in 1899 prior to the opening of the canal, was condemned by the St. Louis Health Department as being not potable, the entrance of the Drainage canal into that water would render that water less valuable for drinking purposes. It is a case of relative conditions.

2178 If water had been declared absolutely unfit for drinking purposes, I should consider that, from a sanitary standpoint, it had a very low value. If I could not get any other kind of water I would give some value to that water. Assuming that the city of St. Louis is so situated that it could get other water, and that the water of Grafton in the Illinois river by the analyses of the city chemist in 1899 was condemned and pronounced dangerous to the public health of the city of St. Louis, what value would you give to that water?

A. If it were really dangerous to health, I should give it a low value.

2180 As I understand it, there is a greater possibility today of the water supply of the city of St. Louis at the intake being polluted than there was before January 17, 1900, by reason of the discharge of the sewage of Chicago through the Chicago Drainage canal.

That probability has been demonstrated within the bounds of scientific judgment; it has not been chemically demonstrated. I have no information that leads me to believe that it has been chemically demonstrated excepting that I understand that certain results of the analyses in general show slight increases in the organic matter, etc., indicating of itself, but not proved. I do not consider that these indications rise to the dignity of proof. I don't believe it has been chemically or scientifically proved that the waters that enters the intake tower today are more injurious to public health than they were prior to 1900. I don't believe it has been chemically or scientifically proved, but I believe that scientific judgment leads us to believe that such is the case.

Q. When scientific demonstration fails to establish a fact then the so-called scientific judgment does not differ from the judgment of a man who is not scientifically advised, drawing his inference from the same conclusion?

A. Where an absolute scientific demonstration is impossible, the next best thing to my mind is a scientific judgment.

Q. Well, can a judgment be scientific when the facts upon which that judgment is predicated, are incapable of scientific demonstration? A. No, sir.

2182 If it could be proven to me that Asiatic cholera germs would not live longer than five or ten days in natural waters under conditions existing, my conclusion that they could reach the intake from Chicago would be changed, but I am not sure at all that the conditions existing in a laboratory experiment would be comparable to those which would exist in running streams.

2184 WILLIAM THOMPSON SEDGWICK, examined in chief by General Crow:

Am not a physician, have studied in a medical school but have no medical degree. Taught physiological chemistry at Yale for one year, etc.

2185 Am a biologist. Scientifically that term implies work upon living things which may be anything from man to microbes. It is a very general term and of course I do not pretend to be an expert in all its departments. Am now Professor of Biology in the Boston Institute. I am an epidemiologist. That term implies an expert knowledge of epidemics, their origin, their characteristics, their scope and everything else relating to them. I have made that branch of sanitary science as related to American cities and towns and the American public, a study.

2186 Am a bacteriologist. Have taught and have had practical experience in that line. In the preparation of the paper I have mentioned on typhoid fever, in Chicago, in 1892, in a general way I had occasion to investigate the physical and sanitary conditions of Chicago with reference to water supply, sewerage and sewer out-falls at that time.

2187 I came to the conclusion mainly from a study of the typhoid fever statistics and the general arrangements of sewerage and water supply that the city was then suffering from one of the worst epidemics of typhoid that ever afflicted any American city and that this pollution was derived from typhoid cases in the city which contributed their sewage to the sewers of the city which emptied either into the Chicago river or into the Lake and in that way, gave occasion for the germs of the diseases to get into the cribs or the intakes of the water supply. I made no very thorough investigation of the Chicago river and its branches. I simply walked along the river at various points and noticed its condition—which was obvious to the eyes and nose. It was grossly polluted.

2188 Chicago sewers are built on the combined plan. This means that street washings and storm water find their way into the sewers and greatly accelerate the flow in the sewers, at the same time, diluting the sewage somewhat. This accelerates the flow and shortens the time spent in the sewers.

2189 I should say several hundred tons of sewage matter are discharged daily into Chicago sewers. The sewage from a quarter of a million of inhabitants goes into Lake Michigan. The remainder is discharged into the Chicago river and from that, into the Drainage canal.

2190 The effect of the sewage now going into the Lake is to pollute the waters in the vicinity of the intake cribs.

I recognize a difference between mere pollution and infection—or what I might call infectious pollution—somewhat as follows: I understand by pollution alone, a condition in which water contains organic matters, or even filth, free from the germs of specific diseases; and I understand by infected water or an infectious pollution of water, or an infectious contamination of water, a condition in which, either with the same or more, or less pollution, the germs of specific diseases are present; so that a water may be polluted, from my point of view, but not infected, or it may be infected and yet to the ordinary eye not polluted. Water contaminated by infectious pollution is dangerous.

2191 Mere dilution will not destroy or eliminate infectious pollution or matter in water. On the basis of dilution alone, I do not consider that the sewage from the Chicago Sanitary district as it reaches the Illinois river above Peoria is at all times rendered pure and safe for domestic use. (Witness expresses himself at length on the question of self-purification of waters.)

2192 There is, at all times, in certain streams, especially, a large measure of self-purification. The subject is a complex and difficult one and the growth of opinion has been to increase our distrust in the efficacy of self-purification of waters or sewage.

2193 (Witness reads from his work on "Principles of Sanitary Science and Public Health.") (Motion to exclude by Judge Johns and Mr. Todd.) Sewage flowing directly from the out-falls of the city sewer will affect the value for drinking purposes of a running stream of water.

Q. State whether or not the sewage from a district as large as the Sanitary District of Chicago would affect the value for drinking purposes of a steam as large as the Drainage canal and as large as the Drainage canal and the Des Plaines river and Illinois river combined, and if so, in what manner?

A. Yes, sir, the mere introduction of sewage into a stream at once creates suspicion as to the—at once throws suspicion

upon the character of that stream, and unless it can be shown that that sewage has been effectually removed by puri-
2194 fication, the value of that stream is distinctly lowered. The water of the Mississippi west of the main channel of said river, below the mouth of the Illinois, is decidedly less valuable for drinking purposes now than it was before the sewage from the Sanitary District of Chicago was run into the Drainage canal and through it into the Illinois river.

The addition of such a volume of liquid as passes through the Drainage canal must materially—must often materially, quicken the flow of the Illinois river; it must therefore hinder effective sedimentation, and thus by shortening the time required for infectious germs to pass through the river, and by interfering with their detention, aggravate the danger of their arrival at the mouth of the river. I should like to say right here, that the time allowed in all these matters is very important, so that any quickening of the flow is a grave consideration. It is not so much distance as time which is the basis of self-purification of streams.

2196 By increasing the flow, sewage or infectious pollution from Peoria and the lower points on the Illinois, might arrive more quickly at the mouth of the Illinois and mingle with the waters of the Mississippi. The clearer the water—other things being equal, the slower the rate of sedimentation of bacteria. I believe that increasing the speed of the current of the Illinois, by the addition of the water of the Drainage canal, would have an effect in increasing the typhoid and liability to typhoid and other water-borne diseases, on the part of the inhabitants of Missouri using the waters of the Mississippi for drinking purposes, below the mouth of the Illinois. Speaking generally, the sewage from cities and towns renders unfit for drinking purposes the waters of a running stream for the purposes of domestic use.

2197 Settling basins alone—not considering anything else, are not recognized as an efficient and adequate means for the purification of sewage to be discharged in a drinking water stream. As to the longevity of the germs of typhoid fever, as a general proposition, in connection with sewage polluted water, our ideas have undergone some change of late years. My ideas have undergone some change. The tendency has been to come to the belief, or has been to show or to indicate a greater and greater longevity. Laboratory experiments have sometimes indicated a short and sometimes a longer longevity. Practical experience has tended to make us believe in a greater longevity than that formerly entertained and having reference to the conditions in the stream, my belief is that in a sewage polluted stream, the typhoid fever germs might live, in gradually diminishing numbers, for weeks or months or even years.

2198 Assuming that the bacillus coli communis is not found in greater numbers in the Illinois river now, than before the opening of the canal, I do not consider that the water is at all times no more dangerous for drinking purposes than formerly. Bacteriological examinations cannot be made at every moment and are at best not absolute guides as to the sanitary condition of the water. Assuming that germs of typhoid fever coming from the sewers of Chicago, might be in large numbers deposited in the bed of Lake Peoria, for the period of a month, I do not consider that typhoid germs would be entirely destroyed at the end of that time. Assuming that typhoid germs coming from Chicago are deposited in large numbers in the lakes and slack water portions of the Illinois river above Peoria, I think at times that flood conditions such as would scour the deposits from the bed of the stream would cause the water leaving Lake Peoria to contain at times more infectious and dangerous pollution than is at present in the diluted sewage entering the Des Plaines river at the Bear Trap dam.

2199 The removal of deposits of sewage matter from the beds of streams has resulted in causing typhoid epidemics. (Refers to the old case of St. Clair river.) I do not consider that the water of the Illinois river, since the opening of the Drainage canal and now, as it enters the Mississippi river, is one which may be used with safety for drinking purposes.

Q. Now, Professor, assuming that the only pollution of the Illinois river was that contributed to it by the Chicago Sanitary District, and having in mind the large amount of typhoid fever in said district, do you, or do you not consider the effects of the time interval, dilution and sedimentation occurring between Chicago and Grafton, would be such as to render the waters as it enters the Mississippi at all times free from liability of producing water-borne diseases in those who drink it?

A. Emphatically not, for the reason that such processes of self-purification, including sedimentation and dilution, as would take place in the Illinois river and above, to Chicago, would be, in my judgment, inadequate to insure at all times and seasons a complete removal of infectious material.

2200 (Refers to the Lowell, Mass., epidemic. Says it was caused by Stony Brook stream running into the Merrimac at right-angles.) Stony Brook stream was much smaller in proportion to the Merrimac than the Illinois is to the Mississippi.

2201 This infection came a very short distance up Stony Brook. It entered the Lowell waterworks and produced an epidemic three and one-half miles below but there was also reason to believe that it reached Lawrence, nine miles further on. I believe that infected water coming from the Illinois river and entering the Mississippi would become mixed with the water so as to menace the health of the inhabitants of the Missouri shore using Mississippi water. I consider it probable that infectious pollution would, at times, enter the intake of the St. Louis waterworks.

2202 During a period of fifteen years prior to January 1, 1900, typhoid fever death rate in St. Louis has not in general been above that of some cities provided with water supplies considered pure and of good repute. Beginning with January 1, 1900, there has been a marked annual increase in the typhoid fever death rate of St. Louis so that it has, during that period, not only been higher than during the previous period of five years, but also higher than at any time in its own history since 1885 and very much higher than the death rate in Boston, with which it previously compared very favorably.

2203 Assuming that the only pollution on the water-shed of the Mississippi and its tributaries, above the intake of the St. Louis waterworks, was that derived from the Sanitary District of Chicago and having in mind the large amount of typhoid fever in Chicago, I believe that infection and dangerous pollution might find its way into the water supply of the city of St. Louis.

2204 Under the same assumptions I believe that typhoid fever germs from that district are liable to find their way into the water supply of St. Louis. (Witness states that experiment made with 107 barrels of bacillus prodigiosus shows that typhoid fever germs can be carried down the canal, the Illinois river and to the intake.) Assuming that an epidemic of Asiatic cholera took place in Chicago, it is possible that the germs of the disease might find their way into the intake of the St. Louis waterworks.

2205 (Recounts details of Plymouth, Penn., epidemic in 1885.)

2206 (Same as to the Lowell, Mass., epidemic. Gives details of Newburyport epidemic. Newburyport is at the mouth of the Merrimac river.)

2207 The cause of this epidemic was the drinking of water from the Merrimac, which had been infected at Lowell, 25 miles away. The Rivers Pollution Commissioners of Great Britain in the report published by them in 1874 state that there is no river in the United Kingdom long enough to purify itself from any sewage admitted to it, even at its source. That stands as one of the axioms of sanitary science today.

2208 The epidemic at Windsor, Vermont, was caused by one case of typhoid fever on the water-shed above, not very far above, a mile perhaps. In 1898 I made a special study of typhoid fever in Pittsburg. They drew their water supply from the Allegheny which is a swift stream with only remote pollutions. A study of conditions there resulted in recommending the filtration plant for the city of Pittsburg, for the reason that in my judgment, infectious materials might be brought to cities which had no filtration plant, from points as distant as Oil City or even more remote—113 miles or more.

2209 The epidemic at New Haven, Conn., occurred about 3 years ago. It was caused by feces washed from a house on the water-shed where there had been a few cases of typhoid fever. The epidemic at Ithaca, New York, we have every reason to believe that the conditions were quite similar to those at Plymouth, and New Haven.

2210 (Refers to epidemic at Hamburg, Germany, in 1892, and the breaking down of the Berlin, Germany, filters, which caused a small epidemic of typhoid fever.) It is a matter universally admitted among sanitarians that running water uncared for and unprotected by special processes of filtration or prolonged and very thorough storage, is liable, if from an infected watershed, to convey the germs of disease. I found in Buffalo, rather to my surprise, a feeling prevailing among medical men that the time was at hand when Buffalo had got to purify her water because of the pollutions put into the lake at Cleveland and higher points.

2211 I think it is a great question whether the people who are using the big lakes have not got to give up the use of them after while. A while ago, Professor Jordan reported practically to that effect for Chicago, and Detroit certainly stands in great danger from pollutions at Port Huron and possibly other points. Cleveland I have been told, although I am not sure of this, is seriously thinking of giving up its tunnels and going into filtration because the water that comes down from above is polluted. It was one of the commonest things that chemists and sanitarians believed and they had reason to believe at that time—that running water, at even modern distances, would so purify itself as to be safe. But Pittsburg, Lowell and Lawrence, and so far as I know, nearly all of the cities that have trusted to that, have been typhoid ridden and today, as I reported at Pittsburg, the distance of 100 miles, or even more remote points may produce typhoid fever. It is not today so much a question of distance. It is the question of giving time for the germs to settle out and die out and it is dilution and time of quiesence, particularly quiesence.

2212 Q. Professor, would the amount of infectious pollution affect the question of time needed, or the degree of danger?

A. It affects the degree of danger. It would not affect the time; that is the time for each individual microbe; of course that is its own individual problem. One microbe coming down from Chicago and resting quietly in the slack water of the Illinois, if it lay there long enough would probably die out—I would say, must certainly die out if it lay there long enough. Of course, someone might not agree with me on that, but I think so; but of course, if a million came down, the chances that some might be carried on by a little freshet or something of that kind before they had died out—for they don't all die at the same time—would be greatly enhanced, and other things being equal, the larger the infection, the more serious the danger.

2214 After a careful consideration of the subject I can say that in my opinion, beyond a reasonable doubt, the principal portion of the increase of typhoid fever in St. Louis, since January 1, 1900, of the principal annual increase, since January 1, 1900, has been due to the pollution of the water supply of St. Louis by the sewage of the Sanitary District of Chicago.

2215 I stated this morning that from 1895 to 1899 the typhoid rate in St. Louis was substantially normal, comparing favorably with similar cities of like situations and of similar size. I should like to add that the word "normal" must be taken in a general rather than in an advanced sanitary sense, for I believe that both Boston and St. Louis are capable of further improvement in this direction, and both are higher than New York and London. From 1895 to 1899 the death rate from typhoid in St. Louis compares favorably with that in Lowell after the introduction of the ground filter water supply. I have no experience that would cause me to believe any running stream can be relied upon, at all times, to remove disease-bearing germs, such as the typhoid bacillus, if the pollution was at all serious or extensive.

2216 The opening of the canal has resulted in the addition of an amount of lake water which will yield 5,000 cubic feet a second at Lockport, passing out of the canal, and this, on the face of it, adds a purer water than that sewage. The sewage is unquestionably diluted, as is shown by the improved condition of the Chicago river, but this water is drawn from the

mouth of the Chicago river and vicinity and that water has long been known to be infected more or less. The problem then resolves itself into this—does the dilution of a presumably often infected sewage, by a presumably often infected water contribute to the purity of the Illinois river? But that is not all. The Chicago river was formerly a sluggish stream. Today it is much less so, and those infectious materials that were formerly put into the Chicago river are today carried with comparative swiftness down the Drainage canal and into the Des Plaines and Illinois rivers. We have further, then, to consider whether sewage, as described above, carried quickly, and in considerable volume, into the Illinois river, does or does not render that river safer than before. My only belief based upon those considerations which I have already outlined in regard to time as a purifying factor is that it is at least very doubtful whether the pouring of the sewage of Chicago, diluted as described, into the Illinois river does at any time improve that river. Looking at it still more closely and considering the larger amount of sewage now delivered, the opportunities for sedimentation, the susceptibility of the Illinois river to
2217 freshets, large and small and in view of the changed conditions brought about by the introduction of this fresher sewage with a larger volume of water, I am inclined to believe that—and further, in view of the frequent extensive pollution of the sewage of Chicago by the germs of typhoid fever.

Q. You mean infection, don't you?

A. Infection of typhoid fever, I should say—I am inclined to believe that the pouring of the sewage diluted as described, into the Illinois river, has not at any time improved it from a sanitary point of view—from the point of view of the health of the people who may use that water on the Missouri shore. I may say that undoubtedly at times it may have improved its appearance, and may seem to have improved its quality; but taking it through the year at all times, at all seasons, I am inclined to doubt exceedingly such improvement—any such improvement at any time. I believe that the danger is contsant, immediate and continuous on the part of the inhabitants of Missouri using the Mississippi river water, by reason of the sewage from the Chicago Drainage canal infecting the water of the Illinois river. (Witness states reasons.)

2218 Dams undoubtedly, so far as they produce slack water or quiesence, favor purification and the disappearance of disease germs for the time being, but if the sediment or sludge is allowed to remain in the stream and is not removed artificially, the chances are good and experience shows that in freshets, it may be returned to the stream and again become a part of it, travel with it and produce trouble below.

2219 The only safeguard is to keep the germs quiet in the sediment at the bottom so long that they shall have entirely died out. We hardly ever know when that is. It is a very weak reed to lean upon. At Lawrence there is a big waterpower supplying immense amounts of machinery with power to run. At times the water reaches back almost to the Lowell sewers—nearly nine miles, and the dam above Lowell, which furnishes the power to Lowell reaches back almost to Nashua, New Hampshire—sixteen miles. The Merrimac in the summer, is a series of mill-ponds, slack water like that, the water used for mill power.

2220 In time of freshets we get our epidemics—when the freshets come down the river and scour it out. We do not have a high typhoid rate in summer when the dams are effective and sedimentation is going on. We get it in the spring, when the pollution is great and the scouring is also great. We also get epidemics in the autumn or after the autumn rains. Lawrence immediately set to work and put in an intermittent sand filter and Lowell put in driven wells. Both are now among the cities having entirely reasonable death rates from typhoid fever. My opinion is that the rate of growth in the Chicago Sanitary District is likely much to exceed, and the total growth is likely greatly to surpass that upon the water-sheds of the Des Plaines, Illinois, Mississippi and Missouri and their tributaries.

2221 I should expect it to be at least ten times as great. I will add to this answer, basing an opinion upon pages 119 and 121 of the Illinois State Board of Health report for 1901, sanitary investigation of the Illinois river and tributaries, I should even be willing to make this figure very much larger, as the increase in rural population given there is less than one per cent; that in urban population outside the Sanitary District of Chicago is 28.2 per cent, and that of the city of Chicago is 54.4 per cent. The urban population as compared to the rural population in this country is increasing very much faster. Now it is one of the most striking facts with which sanitarians have to deal, that villages are growing into towns; towns into cities; water supplies and sewerage systems are being introduced and in consequence of this growth, problems of water supply and sewage disposal are almost everywhere becoming common and pressing. This condition of things is bound to increase. In the older cities, it has already led to serious investigation and litigation, with long and varied attempts at remedial legislation, and I cannot help feeling that with the impending growth of cities and towns in the Mississippi valley, it is a question of the gravest sanitary consequence what becomes of the sewage of the cities and towns in that valley—in or near that valley—and also how their water courses may be kept from pollution and the dangers of infection. (For answer of witness as to effect of increase in population in Chicago to 5,000,000 people, with conditions as they are now, see record, pp. 2221, 2222 and 2223.)

2224 I consider that the Illinois water polluted and infected by the sewage from the Sanitary District has rendered less safe the water supply of St. Louis as drawn at the intake, for the reason that I believe the germs of typhoid fever may and do find their way through the intake into the water supply of St. Louis. Assuming that the population of Chicago Sanitary District covers 3,000,000 people and that the flow through the canal reaches 600,000 cubic feet per minute, I believe that the water of the Illinois river would be less pure and less wholesome as compared with that water at its mouth as found during the past three years. The danger of infection would be increased. If the population of the Sanitary District was increased to 5,000,000 people and the flow of the canal reached 1,000,000 cubic feet per minute, I believe that the water of the Illinois river at its mouth would be less pure, less wholesome and more infectious and less suitable for drinking purposes as compared with the water at that point as found during the last three years.

2225 I believe that a mixture of the Illinois and upper Mississippi river water during their flow from Grafton to the Chain of Rocks takes place at times, such that the water of the Illinois river may find its way to the intake of the St. Louis waterworks. Assuming that sewage from 1,500,000 people living in the Sanitary District should be discharged into the Drainage canal, thence into the Des Plaines and Illinois rivers, Chicago being situated 358 miles from the St. Louis intake, and assuming that a typhoid fever epidemic of extraordinary proportions should become prevalent among the residents of the Sanitary District of Chicago at a time when the sewage from said district is being so discharged into the canal, I believe that such an epidemic would be likely to produce an epidemic of large proportions among those people living on the Missouri side of the Mississippi river below Grafton who use the waters of the Mississippi for drinking purposes. The citizens of St. Louis and the Missouri shore would have a right to regard themselves as in a critically dangerous condition as far as their water supplies were concerned.

2226 The same would apply to an epidemic of cholera. (Witness states that there will come a time when the rivers will get so sewage polluted that mere filtration will not suffice. It will be increasingly difficult to secure good water and to get rid of the sewage, etc.)

2227 Stream flows, in general, will not increase, but rather decrease as time goes on.

2228 (Offers in evidence, certificate showing number of deaths from typhoid fever in St. Charles, Missouri, from July 1, 1899 to January 1, 1903.)

2229 (Same as to city of Davenport, Iowa, from 1893 to 1902, inclusive. Same for Rock Island by months from 1893 to 1902. Same as to Moline, Illinois, from 1893 to 1903. Galena from 1893 to 1903. Warsaw for year 1902.)

2230 (Same for Kansas City from 1893 to 1902; St. Joseph, Missouri, Council Bluffs, Iowa; Omaha and Lincoln, Nebraska, and Chicago.) In regard to my testimony taken yesterday, I will state that the quickening of a stream by the addition of a volume of other water, especially under conditions such as prevail on the Illinois, is a very serious menace to the people of the regions below who use that water. It is my opinion that in spite of the addition of the so-called "pure lake water;" in spite of the greater dilution resulting from that, the water of the Mississippi river is constantly and beyond all reasonable doubt rendered more dangerous to the public health and to the citizens who use it, because of that addition, and under all the circumstances which exist on the Illinois and Mississippi rivers.

2231 The Lowell epidemic of 1890 was caused by the dejecta of one person infected with typhoid fever, contaminating Stony Brook about three and one-half miles above the intake of the Lowell waterworks.

2232 The New Haven epidemic was caused by the dejecta of two or three cases of typhoid in a family living upon the watershed. Their dejecta were thrown out on the ground near by and in the thaw which I described yesterday, were washed into the stream. I think they were quite a little distance from the stream, perhaps 50 feet or something like that. It went only two or three miles down the stream, something like that, and from the stream into the reservoir where it underwent probably a very slight sedimentation. In the Windsor, Vermont, case the infection came from about a mile, from a storage reservoir and were supposed to have been washed into a very small stream—a mere thread of a stream.

2233 In the Newburyport epidemic the pollution was derived from the regular typhoid fever in the city of Lowell. The germs were carried down past Lawrence to Newburyport.

2234 At Zurich, Switzerland, the typhoid fever in 1885 was attributed to disturbance of sediment near an intake pipe and a defective filter.

2235 As a general proposition the urban population is very much more dangerous, very much more efficient in the pollution of the waters than a rural population. It would probably be fair to say that the urban is at least ten times as dangerous. The reason for this is that urban populations are more often sewered and when not sewered, are more often upon streams. The opening of the canal, which has been brought about by cutting through the natural divide between the watershed of Lake Michigan and the Illinois river, has added to the drainage area tributary to the watershed of the Mississippi river as it flows to the intake tower, 63 per cent of the entire urban population; 63 per cent has been added to the amount above the St. Louis intake.

2236 Exclusive of the Sanitary District of Chicago, of the population of the watershed of Lake Michigan, I find the amount of urban population on the watershed of the Mississippi and its tributaries, the Illinois, Missouri and Des Plaines and their tributaries above the intake of the St. Louis waterworks, on the basis of cities and towns by 4,000 inhabitants and more, to be, 2,695,782. According to the 1900 census the population on the watersheds mentioned would be as follows: Missouri river, 1,090,832; Mississippi river above mouth of the Missouri, exclusive of the Illinois, 1,219,645; Illinois river, 385,305. All those added together make the sum I gave you a moment ago.

2237 The mouth of the Lowell sewers is about 9 miles above the intake of the Lawrence waterworks. From that point the water was pumped to the reservoir of the city of Lawrence where it was kept for a period varying from one to a little more than two weeks. If we add to this the time spent in flowing the nine miles we may say that the period of time required for water containing typhoid germs to pass from the Lowell sewers to the Lawrence water consumers was sometimes probably as long as 14 days or more.

2238 Settling basins holding suspected water for longer periods than this one at Lawrence have failed to protect the people using such water from typhoid fever. At Covington, Kentucky the water of the Ohio river more or less polluted on the stream above is kept at times as long as 32 days and yet Covington suffers severely from typhoid fever apparently due to infected water. At New Albany, Indiana, the same conditions exist. The typhoid at Niagara Falls is attributed by every one who is familiar with the facts, to the sewage of Buffalo, although that sewage has passed down a stream one of the most favorable in the world perhaps, for dilution, aeration, oxidation, self-purification and similar processes. I consider the case of Niagara Falls as it is today, one of the most instructive we have. The sewage is well diluted, well aerated, and that for a considerable distance. The distance as I recall it between the sewers of Buffalo and the intake at Niagara Falls is about, I should suppose, 18 miles. It may be only fifteen. (Hypothetical question assuming certain numbers of cities to be situated on the watershed of the Missouri river, giving population, number of deaths from typhoid fever per year, number of miles from St. Louis, and stating that the sewers of all such cities discharge their sewage into the Missouri river, also assuming the same as to the Mississippi and Illinois rivers, and ending with, "State what, in your opinion the sewage from 1,500,000 people of Chicago had to do with the increased death rate from typhoid fever in St. Louis as above stated?")

2249 (Objected to by Judge Johns and Mr. Todd.)

2250 After having carefully considered the question and the assumptions which it contains, I believe that beyond all reasonable doubt the principal factor of the annual increase of typhoid fever mortality of the city of St. Louis since January 1, 1900, has been due to the pollution of the water supply of the city of St. Louis by the unpurified sewage of the Sanitary District of Chicago. In fixing this increase in typhoid in St. Louis I used the method known as that of "mortality percentages" in which the typhoid fever mortality is compared with the total mortality of any given district. Measured upon this basis, the typhoid fever mortality during the years 1901, 1902 and 1903 as compared with that during the years 1895, 1896, 1897, 1898 and 1899 was 73 per cent in St. Louis.

2251 Assuming the same state of facts as embraced in the last hypothetical question and considering in addition thereto the rural population of the watersheds of the rivers mentioned therein, my answer would not be materially modified for the reason that as I stated this morning the wastes of rural life are, speaking broadly, usually disposed of satisfactorily from a sanitary point of view upon the areas within which they arise. Occasionally, of course, a rural contamination may produce an epidemic of typhoid fever, but such cases are infrequent and exceptional.

2252 The conveyance of water from the Lake Front of Chicago and from a population which I have already testified has been estimated at more than a quarter of a million people, now draining directly into Lake Michigan at the rate of 300,000 cubic feet a minute through an elongated conduit reaching from Chicago to the mouth of the Illinois river would, in my judgment, be a source of danger to persons using the water for drinking purposes on the Missouri shore and at St. Louis.

2253 I do not believe it is within the bounds of human possibility for any competent expert to say that in a period of low water in the Missouri river such as is likely to occur next Christmas time, a thaw on the Illinois watershed might not endanger the lives of people using the waters of the Mississippi below the mouth of the Illinois on the Missouri shore at the city of St. Louis by sending to them in that water, the unpurified sewage of the Sanitary District of Chicago. No competent expert either can or will say that any means exist at present by which such unpurified sewage can be warded off from the people on the Missouri shore and the citizens of St. Louis under those conditions.

2254 CROSS EXAMINATION by General Hamlin.

Am familiar with waterworks. Have given that matter some study. The system of purification I would recommend, where the water supply is taken from running streams would be filtration, in some cases, and storage in others.

2255 Storage is the accumulation of waters in great reservoirs so that it may be kept for some time before it is used without any treatment of it. The larger size the better. Filtration would be my judgment as the system for a city like St. Louis. I am of the opinion that there is more or less pollution in all running streams as distinct from infection and where sewage is carried into running streams then there is usually infection. That in my judgment exists in the streams to which I have testified in this case, such for instance as the Mississippi, Illinois and Missouri.

2256 If the cities or towns below St. Louis on the Mississippi should take their water supply from the Mississippi river they would be affected by the sewage of St. Louis, if they took it unpurified. Unless the dilution was so great that the sewage of St. Louis was lost in the volume, I suppose that they would be affected. I attach much importance to dilution alone. It is a large amount of sewage that is discharged into the Missouri river and into the Mississippi above the mouth of the Illinois. If I were to eliminate all the sewage from Chicago and take the Illinois, with the Sanitary District out and its tributaries, and the Mississippi and its tributaries, and combine those waters as they are combined above St. Louis, I should say unhesitatingly that the water is and would be, under such circumstances, a polluted water, and that the chances are that it would be dangerous to the people of the city of St. Louis and the towns below.

2258 At the present time my judgment is that the best process of making this water a potable water would be by filtration.

Q. Well, then, so far as the purification of the water of St. Louis is concerned at present, and rendering it fit for domestic use here, for drinking purposes, the expense of doing that would be the same, whether the sewage of the sanitary district was in it or not, wouldn't it?

A. The probable cost of doing it at present, owing to the conditions on the various rivers and at Chicago would, I should suppose not be materially affected by the addition of the sewage of Chicago to the Mississippi river as those rivers are and as that sewage is today.

CROSS-EXAMINATION by Judge Johns:

I am not a chemist, but I regard myself as a bacteriologist. I consider the chemical examination of water of importance in determining its condition for drinking, under some, but not under all circumstances.

2259 A chemical analysis of the waters of the Missouri river at times might determine whether such waters are polluted and at times it might not. The same answer would apply to the the Mississippi river.

2260 Sometimes I can determine from a bacteriological examination of running water whether it is polluted and sometimes I cannot. I could determine from my examination of the evidence as to the bacteriological examination of the waters of the Missouri whether the Missouri is a polluted stream but I very much prefer to do it in other ways. I could at times, I say, but when common sense comes in, I like to use that. I would make the same answer as to the Mississippi river and the same answer as to a joint consideration of chemical and bacteriological examination. A chemical analysis and bacteriological examination of the waters of the Missouri and Mississippi rivers I should not consider as competent at all times to determine the qualities of the waters for drinking purposes.

2261 I believe that waters of running streams, sewage polluted, purify themselves by the flowing of the streams to a large extent under favorable circumstances. The rapidity of the flow would have something to do with the degree of purification. It is the time factor which comes in and that would be profoundly modified by the rapidity of the flow. Numerous reaches where the flow of the water was extremely sluggish and occasional dams checking the water would contribute to the purification of it. Such reaches and dams would contribute to the purification by other means than sedimentation, by detaining the germs present and thus favoring their dying out if they lay there long enough to die out. Mere detention apart from sedimentation would be a factor in this time factor I have spoken of.

2262 If near a given river there were numbers of small lakes or ponds which filled up during the overflow or high water of the river and which contributed to the flowing stream of the river, when the water subsided, they would contribute to the purification of the stream in the proportion in which the supposed lakes and ponds afterwards contributed to the current of the stream. In times of flood, it would certainly contribute to the purification of that part of the water which was over lakes. If there was a flod in the Illinois river in which the waters overflowed the banks and spread out in the bottoms which continued for four weeks and in the bottoms there is no perceptible current of the river those portions which stood upon the bottoms would certainly be purified somewhat. They would be purified so far as the sewage is concerned very considerably. I am familiar with the general physical characteristics of the Illinois river from studying maps and talking with men who have been up there.

2263 I understand that the bottom lands or the overflowed lands of the Illinois river are very considerable. The fact that the Illinois is a sluggish stream in its overflowed stages, that there are several dams and at times much so-called slack water, that in reaches of the river which are not affected by the back waters of the dams, there is in ordinary stages, in many places, and for long distances, a very slight fall, would aid in the purification of the waters of the Illinois river under ordinary conditions. The amount of dilution that would make sewage polluted water safe for drinking purposes is a pretty hard proposition. I do not think that I can answer that except to say that a very large dilution is required to make it reasonably safe. One gallon of sewage from Chicago to 100 gallons of good water would not make that water reasonably safe for drinking purposes. One gallon of sewage to 200 gallons of water I should not consider safe. I hardly know what to call reasonably safe.

2264 One gallon of sewage at Alton might pollute the waters of the Mississippi at the intake tower so as to make them unsafe for drinking if it was typhoid fever infected. (Same as to one gallon of sewage at St. Charles, Missouri.) Knowing that one gallon of sewage from St. Charles infected with typhoid germs had been put into the Missouri river, I should consider the water at the intake unsafe, as a general proposition, provided, of course that I did not know when that gallon was coming along.

2265 Assuming that I knew a gallon of sewage infected with typhoid germs was put into the Missouri river at St. Charles at a certain time and that I knew when that water would reach the intake tower, as a general proposition I would consider the water at the intake tower at the time of the arrival of this water from the Missouri as unsafe for drinking purposes. As to the same amount of infected sewage from Kansas City, which is between 400 and 500 miles away, I should not want to drink the water at that time when it was expected at St. Louis but I should not be willing to say, as a sanitarian, that that was unsafe for drinking.

Q. Then you are a little more particular as to yourself than as to the community in general?

A. No, but others are not as particular as I am.

Q. Well, having an equal regard for others, as for yourself, you would say that the gallon of sewage put into the waters of the Missouri at Kansas City, was unsafe, would you not, at the intake of St. Louis?

A. Assuming that the water was to be taken at the intake at the time that the arrival of that polluted water might be expected, yes, sir.

Q. If a gallon of sewage were put into the Missouri river at Omaha, Nebraska, and you knew when that water would arrive at the intake tower at St. Louis, would you consider that water unsafe for drinking purposes if the sewage were typhoid infected?

A. I don't know how far that is. It is farther away—it is six or seven hundred miles.

2266 A good deal would depend upon the flow of the Missouri at that time. If it were in flood, I should probably not consider that unsafe. If the Missouri was at its ordinary stage, I do not know whether I should consider it dangerous or not. I should have to think that over. I should want chemical and bacterial analyses of the waters and I should want to know conditions more than I do now, the conditions of purification en route, etc. Taking my knowledge of the Missouri river and assuming that a gallon of sewage was put in that river at Omaha when the river was at its ordinary stage and that the sewage was typhoid infected sewage, when the water arrived at the St. Louis intake, I would consider that water unsafe for drinking purposes.

Q. If, in the year 1901 there were 13 deaths from typhoid fever at Lincoln, Nebraska, 58 in Kansas City, 6 in Omaha, 12 in St. Joseph, and 5 in St. Charles, and the typhoid bacilli in each of these cases, went by some means into the waters of the Missouri river, and some of them arrived at the intake in St. Louis, to which one of the six towns would you prefer to ascribe the bacilli arriving at the intake?

A. In answering this question I should have to say in the first place that I should not have any preference in the matter, except such as came from study of the facts laid down, and a weighing of the probabilities as to the origin of each of these— as to the part played by each of these. Other things equal, the nearer the infection, the greater the probability of derivation from that source. The question, however, is a very complicated one, inasmuch as it assumes a large number of cases in the upper regions of the river, and a small number at St. Charles, 47 miles away, as I believe. I should expect, as a result of the consideration of all the circumstances, that I should be entirely unable to assert any preference in the matter or to determine from which of these places the bacilli had come. If found, they would be more likely to have come from Kansas City, because that would mean 580 cases in Kansas City and 50 cases in St. Charles, in round numbers, assuming a mortality of 10 per cent and the likelihood of one getting into the intake at the Chain of Rocks would I believe be greater, all things considered, from 580 cases at that distance than from 50 cases at the other distance. It is a matter, however, almost entirely of guess work.

2269 Considering that Kansas City is 403 miles from St. Louis, I could not say positively that any of the typhoid bacilli would arrive at all. I could not say positively that none would arrive. I don't know whether they would or not. I have an opinion and that is, that they would. The greatest distance that I now recall that typhoid bacilli have been transported by running waters and caused infection in some water supply is that of the Detroit epidemic in which it was apparently well established that the infection was conveyed for about 57 miles. The assumed and supposed distances, however, are very much more than that. For example at Pittsburg, I myself supposed and assumed that typhoid fever germs might have come as I said in my report, from Oil City, which was 113 miles, or even, as I remarked, from points much more remote. That is, there are cases on record where the sewage of towns above, apparently influences the typhoid death rate of towns below, and where no epidemic has ever happened or been traced, conclusively fastening the one upon the other.

In the present state of the subject I should not be willing to set any limit as to the distance typhoid bacilli might travel and at the end of their journey be of sufficient strength and vitality to communicate typhoid fever to people who drank the water.

2271 The real problem would be not so much the distance as the time. The Alleghany river is a swift stream—those 113 miles were covered quickly. It was a babbling stream most of the way, scouring the stones and while I was willing to believe that the typhoid fever in that case came as far as 113 miles, in another case with a slow stream I would not be willing to suppose that they had come fifty miles. I based my opinion that the typhoid bacilli came from Oil City on the rate of flow of the river largely and on my knowledge of the life history of the typhoid bacillus. There is such a thing as accurate and certain knowledge as to the life history of the typhoid bacillus in running water. I know, for example, that they may live to pass from Lowell to Lawrence—nine miles.

2272 In the Lowell and Lawrence case, the waters were polluted, all told, by about eight or ten cases.

Q. Well, your examination of the cases at Lowell and Lawrence excluded every other possible consideration of source of contamination than that which you discovered?

A. I tried to, and I believe I did.

Q. You didn't consider that it was possible that typhoid infected urine or dejecta might have been put in the reservoir or waterworks of either one of the places? A. No, sir.

2273 Assuming that some malicious person had injected typhoid bacilli into the reservoir at Lawrence or Lowell, which it is possible they might have done, those cases do not afford an accurate knowledge of the life history of bacilli.

2274 I wish to make it clear, however, that a malicious infection of the Lowell reservoir would not have invalidated my conclusion in regard to the Lawrence epidemic. From Lowell to Lawrence is 9 miles along the Merrimac river. The community living on the river is more densely populated than rural districts of Missouri. It is within the limits of possibilities that persons living near the Merrimac, between Lowell and Lawrence, might have had typhoid fever and that their dejecta might either be thrown into the river or washed in.

2276 (Witness is cross-examined as to the cause of the Lowell epidemic.)

2282 Q. In reporting upon the condition of affairs at Pittsburg and the remedy to be applied, did you exclude all considerations except the existence of the Alleghany river, and the flourishing towns above Pittsburg? A. I did.

Q. And without knowing whether there was typhoid fever in any one of those towns, or an excessive rate of typhoid fever in any one of those towns, you ascribed the typhoid fever in Pittsburg to the infection of the Alleghany river from towns above it?

A. I do not remember whether there was any or not; whether I based my conclusion upon that partly or not; but in any case even supposing there had been an excess up there, I should have come to the same conclusion, because they were pouring regularly a certain amount of sewage into the stream. All that is necessary to make the waters of a running stream

unsafe as to typhoid fever, is the fact that the sewage of populous places above is poured into the river, broadly speaking, without regard to the fact as to whether there is or has been typhoid fever in any of the populous places above where the sewage is poured into the river. In the epidemic at Detroit my knowledge is taken from books and publications and conversations. The St. Clair river is a passage way for the water of the three great lakes on their way to Lake Erie. I do not know that on each side of it there is a very flat country, full of marshes, that in these marshes and dwelling about them there is a large population of fishermen, that the St. Clair flats are dotted with club-houses, the resort of all classes of people during certain seasons of the year. It seems to me that something of that kind was referred to in the paper which described the epidemic. I understand that the papers which described the epidemic and the persons to whom I talked, exclude all these considerations from the determination as to the cause of typhoid fever at Detroit. I presume they took the most easily ascertained and most prominent possible cause and ascribed to it and to it alone the entire increase in sickness, that would be good sense. I was perhaps a week in Chicago investigating the cause of typhoid fever. I made very little investigation except to study the general situation, but I secured the reports of the board of health and compared the typhoid fever death rate in Chicago with that in other cities. I also inquired into the water and milk supply and other possible factors and then bringing the results all together, arrived at my conclusion jointly with Mr. Hazen. I attributed the abnormally high death rate from typhoid in Chicago
2285 after excluding, as well as I could, other considerations,
to the infection of the water supply by the sewage of the city. I discovered that typhoid fever had nearly always been very high in Chicago, that it never had what might be called an average rate of typhoid. At times, when it was lower than the general average of a series of years I ascribed the typhoid fever to occasional limited pollutions of milk supply, food supply, of the air and of the water and to some minor factors. When the

average rate of sickness in Chicago was less than the usual rate I did not attribute that solely and entirely to the infection of the water supply.

2286 When it rose above the average and far exceeded it, I attributed it to the water supply as a general proposition. The curve or line of typhoid fever in Chicago has been very irregular, always high as compared with cities having a very low, or as compared with most cities having purer water supplies, but occasionally rising rapidly to much higher points. I was led to believe that these rapid and unusual rises were due to the washing out of sediment from Chicago river into the Lake and an unusual contamination of the water supplies by such dislodged sediment or other fecal materials conveyed to the intakes.

Q. Did you compare the statistics, or examine the statistics as to the rain-fall in Chicago and find that such rain-fall was coincident with—or that the increase of typhoid fever actually followed a violent rain-fall, and a sudden rise in the Chicago river?

A. As I remember it, it did so in some cases, and enough to confirm us in the general belief.

If, by pathogenic germs you mean those of well defined infectious diseases, I never discovered such germs in running water.

2288 Water-borne diseases are such as are capable of being transmitted by water or which are capable of being conveyed from one person to another and from one community to another, by means of water as a vehicle. Typhoid fever and Asiatic cholera may be conveyed in this way. It is probable that some others may be conveyed in this way, but the evidence is far less clear than it is in regard to these two diseases. Asiatic cholera is an infectious disease, and it is believed may be
2289 communicated by the air or any of the other means by which typhoid fever may be communicated.

Asiatic cholera in Chicago is of very rare occurrence today, formerly, however, it prevailed very seriously in Chicago. I don't recall that it was ever serious or existed at all except in

1848 or 1847. Inasmuch as Asiatic cholera is by no means an exterminated disease, it might turn up in a population like that of Chicago at almost any time and the danger to the citizens of St. Louis under the existing conditions would be grave. The danger to St. Louis would not depend wholly upon the existence of Asiatic cholera in some one of the streams from which St. Louis derives its water supply. There would be danger of conveyance by train and in articles of merchandise but I should think that the most omnipresent—the most serious danger, would be from the water supply.

2290 The danger by train and by handling of merchandise must be added to the possible cause of typhoid fever anywhere. It is a possibility that a person in San Francisco whose hands were infected by typhoid fever germs, might arrive in St. Louis and spread the disease, or if he carried such germs in his clothes, or if some person packing goods in San Francisco should have typhoid infection on his hands, it might be communicated to people in St. Louis, New York, London, St. Petersburg, Moscow, Karthoum, by way of Moscow, and Nijni Novgorod. It might be conveyed as far as that, if he did not wash his hands en route. I see no reason, if he did not free himself from infection, why he might not convey it around the world. In a trip around the world, say in sixty days, I believe that they might convey it around the world and out of their habitat and away from anything in which they are known to essentially support themselves and that these germs would live.

2291 I should be unwilling to say that Asiatic cholera might not also be conveyed around the world under certain conditions, in other things than in water. Say, in clothes of persons traveling, or in merchandise that went around the world, and a great deal would depend, of course, upon the time and conditions to which the germs were subjected, but in the present state of our knowledge, I see no reason why they might not be transmitted even as far as that in those ways under favorable conditions, of course. A person traveling with ordinary speed around the world I should expect would leave some of the bacteria en route. I don't know that he would arrive with some of them. The chances are that he would not. If he was a respectable person and traveling around the world, he would probably take a bath and change his clothes.

The bacilli coli communis are common in the sewage polluted waters of Massachusetts, or some of them.

2292 There is no geographical limitation to the existence of bacilli coli communis in polluted waters, so far as I am aware. Whenever there is sewage polluted water, there either may be now or may have been the colon bacillus. It is not pathogenic in the sense in which I define pathogenic, although it is put down in some of the books as capable of producing disease.

It is not the cause of a well-defined specific disease, nor
2293 is it, to my knowledge, the cause of ill-defined and general
diseases. I do not regard the bacilli coli communis a standing or floating menace or any other kind of a menace to the city of St. Louis, in themselves, inasmuch as every citizen of St. Louis has millions of them in his alimentary canal. I do not intend to be understood as testifying that the bacilli coli communis in themselves were dangerous to the health of the city when found in the waters supplied to the inhabitants of the city for drinking purposes. In order to become of themselves a menace, they would have to be capable of producing disease. For practical purposes we may acquit the coli communis of being a pathogenic germ and I would acquit them in the Illinois river, of being pathogenic for practical purposes.

Q. Do you mean to say that the typhoid deaths of the city of St. Louis since the year 1900, considered annually are about 73 per cent increased over the deaths from the same disease before?

A. Not exactly that. What I did say was this: that the increase in the average percentage mortality from typhoid fever in St. Louis, reckoned annually since January 1, 1900, was about 73 per cent above the average percentage mortality during the previous five years.

2294 (Explains method employed in computing percentage of mortality from typhoid fever in St. Louis.)

2296 (Upon being examined as to the limit of 4,000 as a basis fore the estimate of urban population, witness stated as follows:) I have no doubt that on the Illinois, Mississippi and Missouri rivers there is a considerable number of people residing actually upon the banks and the water, engaged in fishing largely and sometimes in agricultural pursuits, and all of whose sewage goes directly and without any intermediation whatever, into the rivers. I have no doubt that among such people there is a considerable amount of typhoid fever.

2297 The percentage of typhoid fever deaths in the assumed river population would be somewhat larger than the same per cent of the assumed urban population having the same water supply. In my testimony I did not calculate any percentages on the urban population. What I did say was that the addition of Chicago to the urban population upon the river above St. Louis was an addition of about 63 per cent.

2298 In making these figures, I took the census as I found it. I do not know whether in the census they counted this river population that is floating about.

2299 The rural population, so-called, contributes very largely to the pollution of streams in whose watersheds they reside, using that word as distinct from infection.

2300 As to the method of disposing of sewage in communities having a population of less than 4,000, spoken of by me in my direct examination, I do not know whether that process prevails in the villages and towns along the Illinois, Mississippi and Missouri rivers, having a population of less than 4,000 inhabitants. It is a fact in sanitary science that the pollution of rivers by what we term the rural population is a very large factor in the consideration of the amount, and degree and kind of pollution, but scientifically, considering infections I do not take it so much into account, because in a rural population infection, to begin with, is less common. In the second place, owing to the time factor which is apt to come in, in the partial purification of pollutions, the infectious materials may be destroyed. I have no knowledge as to whether the mortality percentage along the Illinois river is greatest in the urban or in the rural population. Take a common rural population—meaning by that a population not in a village or city of 4,000 inhabitants or more, such a population enters very largely into the consideration of all sanitary questions in regard to the pollution of rivers and into the consideration of the infection of rivers. I think I have the means of determining what per cent the rural population of the Illinois river watershed adds to the population of the watershed of the Mississippi river. I don't know that I can lay my hands on it at this moment but I think the data for such a comparison exists.

2302 I have not in my mind approximately what that per cent is. I have very definite ideas of the time in which the typhoid bacilli do actually live in the waters of running streams. I think I have traced the typhoid bacillus by its effects from the place and time of its origin until it ceased to exist in any given case. I might refer to the Newburyport case.

Q. What was your evidence in the Newburyport case?

A. My evidence was of this character, I traced a small epidemic in Newburyport to a larger epidemic in Lowell, and I knew by the history of the disease in Lowell and in Newburyport, when I had a right to assume that the germs in the flowing water had gone by. Still, I must confess, I do not know how long they remained in the sediment of the river, if any were deposited.

2303 There was reason to believe that it was constantly more or less infected from the sewage of Lowell. The distance is about 30 miles from Lowell to Newburyport. The Merrimac in places is a rapid stream. There is one dam between Lowell and Lawrence and the stream is a tidal stream at Newburyport but not at Lowell.

2304 I should not say that it took the typhoid bacilli injected into the river from the sewers of Lowell more than two or three days to reach the intake at Newburyport. I should say not less than three probably and should not suppose it would be more than five or six but I really do not know. In my direct examination, I stated that at Lawrence, the germs came down nine miles and were pumped presumably into the service reservoir of Lawrence and by comparing the time elapsing between the corresponding periods of the two epidemics in Lowell and Lawrence, and knowing the custom of the water department of holding the water in the reservoir, I have estimated that the bacilli may have lived in the water for between one and three weeks, covering a distance of perhaps ten miles.

2307 If any one maliciously threw typhoid fever germs into the stream with the expectation that they would kill people below, and if they did kill people below, I should convict him of murder.

Q. That is, if the particular typhoid fever germ which he threw into the river were shown by the evidence beyond a reasonable doubt to have produced it?

A. If the evidence was conclusive, that is the act had produced the death of innocent persons, if the act was knowing and intelligent, and if he knew that his act was of such a character as would be likely to produce the deaths of such persons, and if he were sane, I should. In this particular case, I should not expect to detect the germs. Theoretically, I know that the bacilli that killed this suppositious man, he might have received from any other of a dozen different sources.

2308 I hold in a case of this kind, it is not necessary to discover the bacillus. It is sufficient to get the facts of epidemic and connect them as is done constantly in sanitary science, and I think might be applied legally in a case of this kind. My first step would be to exclude every reasonable possibility from my mind as to the derivation of the death-dealing bacillus from some other source. I should also consider that there was no isolated case, any infection from washing infected hands in the river and any other of a thousand ways in which the bacilli might be put in the river.

2309 I want to give you the exact dates in the Newburyport case. The supposed causative cases appeared in Lowell in December, 1902, and reached Lawrence and Newburyport in January, 1903. From my own personal experience, I do not know of a case of typhoid fever which was certainly traceable to typhoid bacilli which had existed for any length of time in the sediment of a running stream. My opinion as to whether typhoid bacilli do exist in the sediment of running streams is derived partly from my reading and partly from my general biological and bacteriological acquaintance with the typhoid bacillus and with bacteria in general.

2310 I do not think it is stated in the reports whether in the Zurich instance, the bacillus of typhoid fever was actually discovered in the sediment which was disturbed at Zurich. I think I have read of some cases in which it was believed that the typhoid bacillus had been discovered in sediments of a running stream. I do not remember now, in what book, and I am not even sure that such was the case. Other bacilli have been discovered in great numbers in the sediments of running streams very frequently and with great ease.

Q. And because other bacilli do live, you reason that the typhoid bacilli may live, or do live in the sediments of running streams?

A. I reason partly by analogy; partly from the general behavior of bacteria in organic materials, and partly from the epidemiological evidence that I have referred to. We have a great deal of evidence outside of the Zurich and Detroit cases. The fact that the beginnings of freshets are very apt to cause epidemics of typhoid fever in communities using the water derived from such freshets, indicates very clearly that heaps of material at the mouths of rivers or in running streams when stirred up may and do cause epidemics of typhoid fever. It is a well known fact that washing in of materials from banks of streams has, as I understand, produced some of our worst epidemics. I should attribute epidemics in an uncertain proportion to both surface washings and sediment washing in case of freshets.

2312 I do not recall any cases in which the bacteria of typhoid fever has been discovered and identified in the sediment of running streams. First experiments in laboratories showed a short longevity for typhoid bacillus but as time has gone on the opinion has I think grown among the bacteriologists—it certainly has in my mind—that those earlier experiments upon the germs were based upon unnatural conditions and that under perhaps slightly different conditions, in mud or manure, the typhoid germ must live very much longer than we had at first believed.

2313 Bacteriologists differ among themselves, like other men. They are at war among themselves as much as doctors, more or less. I don't know that I ever heard any bacteriologist say that the typhoid bacillus would live in a journey of 400 miles in running water, nor 300 miles, because such assertions would be fool assertions.

2314 He doesn't know whether they would live in such a journey or not unless he knows more about the conditions. I have said over and over again that it is not so much the distance, it is the time that comes in and bacteriologists don't go around making assertions of that sort—at least, the good ones don't. I am ready to assert my positive conviction that typhoid bacillus may and do live to make the journey from the Drainage canal through the Illinois river down the Mississippi, to the intake tower at St. Louis.

Q. Based on what evidence?

A. Based on the whole chain of evidence which I have in my possession regarding the sanitary history of Chicago, the character of the water used to dilute the sewage of the city of Chicago, the character of the Illinois river, especially as to being subject to floods, and the character of the Mississippi river into which the Illinois empties, and with which in my opinion, the Illinois freely mixes, so that such germs may be carried alive and virulent, from the people of Chicago to the intake tower of the St. Louis waterworks, and further, upon the vital statistics of the city of St. Louis, as I have studied and compared them with the vital statistics of other communities.

2315 I think I may say it is an extension of the theories as to the existence and time of existence of typhoid germs in running streams but I am not ready to say that it is a very large or remarkable extension, all things taken into consideration. I should say the same thing if an identified body of sewage or water, took five weeks to make the journey or five months. If the time required were one year, I should want to know a good deal about the sediment and the particular conditions that prevailed during that year. I can conceive of conditions which might destroy the germ en route during that time or even before that time, but I can as readily conceive of other conditions which might prolong its life—for example, the pouring of a large quantity of acid from manufacturing wastes down the canal during that year might conceivably destroy the typhoid germs in the water and in the sediment. On the other hand, the pouring down of an unusual amount of organic matters from the stock yards, or from some other place, might so enrich the water as to sustain the life of the germs, perhaps even leading to a greater duration of life than that that you have stated. The fact is that the conditions which have got to be considered in a case of this kind are so many that it is impossible to make categorical answers which will have any real value, unless all of the conditions can be assumed, and that is impossible.

2316 If the journey took one year I think the chances are good that for the greater part, the germs have died out, but I should be afraid that some might still be alive, if they came in Chicago sewage, in conditions existing in the Illinois river—I should expect that some might still be alive—a small percentage. I should say that in regard to the periods beyond a few weeks or months that in general the mortality among the typhoid bacteria would be heavy but that I should never feel certain personally, even after one or two years, or possibly longer, that some of those were not still alive there. I, as a biologist and sanitarian, can see no reason why these little fellows may not, under some circumstances, have their lives very extensively prolonged, and at the present state of our knowledge—indefinitely prolonged. Of course. I mean in diminishing numbers and with a small percentage left.

2317 I think we may fairly assume that there is a diminishing virulence, but there again we are very much in the dark, as we are in a good many of the finer points in bacteriology and medicine. The best place for the typhoid bacilli to thrive and multiply is in the human body. They thrive also in our laboratories under favorable conditions for that purpose. Nothing is known as to their multiplying in nature outside of laboratories. The general acceptation of the most modern bacteriologists is that they do not multiply in running streams. It is commonly supposed that Asiatic cholera lives in the polluted water butts of Calcutta the year around and I think the same thing was found, or believed to be found in Egypt.

2318 Am fairly familiar with the bacillus prodigiosus. There are what some bacteriologists believe to be varieties, and others hold them to be distinct species. On the whole, I believe it is a very well defined species, with no troublesome varieties turning up.

2319 Do not know whether it exists in the waters of the St. Lawrence river, Lake Erie, Columbia river, Lake Michigan or Missouri river. In other words, I may say I do not know whether it exists, but that in my experience, it is not found ordinarily, so that while I don't know whether it exists in those places or not, I should be very much surprised to find that it did exist there, unless exceptionally and rarely. (Same answer applies to the Mississippi and Illinois rivers.) I have never found it in natural waters of the United States.

2323 If numbers of bacillus prodigiosus—large numbers—were injected in a stream and the numbers were large enough to stock the stream pretty well, it would not be very surprising if they were taken up the stream by boats, for instance in the process of washing the decks of the boats, by pumping water from the river. If they were in any water that was conveyed up the river, I should expect them to come with it.

2324 My opinion is that if the waters and sewage coming from the Drainage canal should be wholly diverted into another channel so that none of such waters could enter into the Mississippi river or into the intake of the St. Louis waterworks, and that the only waters that could enter such intake would come from the Missouri, Mississippi and Illinois rivers—excluding the water and sewage from said Drainage canal, that such waters would not be suitable and safe for drinking purposes, in their natural state, or as they enter the intake tower of the St. Louis waterworks.

2325 In my judgment it is entirely possible and practicable to so treat the waters which now enter the intake of the St. Louis waterworks that they shall be suitable and safe for drinking purposes on the part of the citizens of St. Louis. I have taken pains to satisfy myself that the present system of supplying water to St. Louis is now substantially the same as it was prior to January 17, 1900. In my judgment it is now and was, prior to January 1, 1900, insufficient for adequate purification.

CROSS-EXAMINATION by Mr. Todd:

The death rate of typhoid fever is taken as a basis of calculation in preference to taking the number of typhoid cases, as a matter of taste largely.

2326 Investigations have been made and results obtained by various observers and the general result is that the number of microbes discharged in a day from a normal human being is very large—enormous—and that in cases of typhoid fever, the probable discharge is also very large.

2327 By a normal typhoid death rate I mean a death rate which places a city or town having it, in the ranks of cities and towns having good water supplies and good general sanitary arrangements and conditions. This is the sense in which I used the expression that the rate of mortality in the city of St. Louis was normal. If there were 215 deaths and 788 cases in 1893 that would not be a normal number of cases, it would be too small. That means that the physicians did not report the cases.

2327 If it should appear that in 1899 there were 130 deaths and 908 cases of typhoid, that would come near being normal, but here again the number of cases is rather small for the number of deaths. The normal death rate from a sanitary standpoint for typhoid in a city with the population of St. Louis, would be about that which St. Louis had in 1895 to 1899 inclusive, although it might be lower than that under the most favorable circumstances. I attribute the presence of typhoid in St. Louis from 1895 to 1900 to a variety of causes. For example I have no doubt that the water may have contributed something to the net result. Milk, oysters, secondary infection,

2328 dirty hands and that sort of things, from person to person, and also infected foods other than milk and oysters, such as watercress, celery and unwashed fruits, flies and animals and other factors.

2329 I cannot give you the name of any French or English bacteriologist who has discovered the germ of typhoid in an oyster.

2333 I must frankly say that I believe a part of the rise in typhoid cases in 1900 was due to the same cause which operated at the end of 1899. The amount of typhoid fever in St. Louis at the end of 1899, in a city of this size and considering the season of the year, is entitled to be called an epidemic, but it was somewhat above the ordinary.

2334 I should consider an increase such as I have actually found in typhoid in St. Louis for the period since the Drainage canal was opened, 73 per cent, a large increase. (See record 2335.)

Q. If the number of deaths in 1890 was 277, to what would you attribute this high death rate?

A. I don't believe I should be able to answer that question. I would have to give it up.

2341 Typhoid fever may be conveyed by small particles of sputum from the patient, flying off in the air and by kissing. There are at least two or three thousand wells in St. Louis. I have no doubt that some of them are located in the neighborhood of out-houses. I exclude altogether the 2342 wells of St. Louis as producing any important part of the increase of typhoid fever since January 1, 1900. (For reasons, see record 2342 and 2344.)

2343 Q. How many wells in the city of St. Louis have you investigated personally, that privies drain into? A. None.

Q. How many privies in the neighborhood of those wells, within these three years, have received the excreta of typhoid patients?

A. I don't know..

Q. How many people living in the houses where these wells are located and drinking the well water, have contracted typhoid fever from them, if you know?

A. I have no means of knowing.

Q. And in the absence of knowledge upon those three propositions, do you claim as an expert sanitarian, that your conclusions in answer to my former question were established beyond a reasonable doubt? A. I do.

2344 MR. TODD: If conditions existed in any of the wells of St. Louis where fissures appeared, permitting the conamination of privies to enter the wells, such as you have inlicated in part of your answer, have you investigated to ascertain whether that condition obtains or not?

2345 A. I have not. If that condition should obtain, then in my opinion, it would be a serious menace to the health of the people drinking that water. I do not know whether in the three thousand wells in St. Louis, that condition obtains in one or more wells.

2346 I do admit that conditions may exist whereby the water of a well may be contaminated as well as infected.

2351 Q. Assuming that in the different sanitary districts in the city of St. Louis, where the typhoid was high in omparison with the other districts, that there existed a number of infected wells, would not that condition account for the typhoid in St. Louis for 1900, 1901 and 1902?

A. It might, if one were justified in making such an assumption and excluding from the same assumption the possibility of the occurrence of infected wells in other districts. (See pages 2350 and 51 for the number of wells and number of deaths from typhoid in 1900, '01, '02, in the seven sanitary districts composing the city of St. Louis.

2357 (Witness is asked question giving the number of deaths for 1900, '01, '02, in Lincoln, Kansas City, Quincy, Des Moines and Indianapolis from typhoid fever, and stating that those deaths indicate a gradual rise from 1900 to 1902, and asking the witness as to the cause of this apparent increase.)

2358 Objection by Mr. Jeffries and General Crow.

A. Having made no investigations of the sanitary conditions and causes of the typhoid fever in any of the cities mentioned, I am unable to give any reasons for the facts stated. In the case of Kansas City, it is apparently not very large and may be due simply to the rapid increase in population.

2359 MR. TODD: Professor, in the hypothetical question put to you by Mr. Jeffries, and the tabulation of typhoids from each of the cities located on the water-shed of the Missouri, Mississippi and Illinois river, exclusive of the sanitary district of Chicago, would you regard the excreta of the typhoids that appeared in each one of those several cities, if emptied into the rivers, upon which those cities are located, alone sufficient to make unsafe the water supply of St. Louis? By that I mean any one city, as distinct from all the cities?

A. I should certainly regard the rapid and practically continuous pouring of typhoid excreta from such a number of cases as appears to have occurred in any of these cities, as contributing to make the water supply of the city of St. Louis unsafe, but inasmuch as this is purely a theoretical question, and as a matter of fact, such a condition does not, and in the nature of the case, cannot exist, and furthermore, keeping in mind the partial purification of the water supply of St. Louis after it has been taken from the river at the Chain of Rocks, I cannot say whether I should or should not under real conditions, so regard the water.

2360 I have no doubt that the number of typhoid fever deaths and cases existing during the three years mentioned, 1897, '98, '99, upon the watershed above the intake of the St. Louis waterworks, which numbers would indicate perhaps between three and four thousand cases, annually, would render the water supply of the city of St. Louis, if taken at the Chain of Rocks and delivered to the citizens unpurified, somewhat unsafe and somewhat dangerous, but it must be borne in mind that many of these deaths occurred at very remote points. It must be remembered furthermore that at no one time was there anything like any such number of cases as three or four thousand, and that for some periods, the number of cases and deaths upon this immense watershed must have been comparatively very small, so that there may have easily been times during those years, or any one of them, when the water was neither unsafe nor dangerous. Putting all the facts together, then I should say that inasmuch as at no time was there any very large number of cases or deaths upon the said watershed, exclusive of the sanitary district of Chicago, so far as I am aware, and inasmuch further, as the water taken from the intake tower at the Chain of Rocks was considerably purified by sedimentation before its delivery to the people of the city, the danger at any one time could not have been very great. In point of fact, the statistics show that during those years typhoid fever in St. Louis was, for St. Louis, remarkably low, and the water probably better than for many years previous, excepting the years 1895 and 1896, when the conditions of the intake were similar to those which prevailed during the three years under consideration.

2361 I do hold that the pouring in of raw sewage materials into a drinking water stream is likely to render the water below unsafe for drinking purposes.

2363 There may be, however, times when such water could be used with safety owing to the so-called self-purification en route, by dilution, sedimentation and the time factor. Assuming the conditions to be as we have considered them, during the years 1897, '98, '99, I should not, as a sanitary engineer, be able to state the times when it would or would not be safe for the citizens of St. Louis to use the water that comes from the intake. I should probably not have recommended it for drinking purposes or as a safe drinking water at any time during that period, without treatment and purification, inasmuch as one would never know—assuming that typhoid bacilli once found access to the river above in these large numbers—with any precision or certainty, that these would have been effectually removed. I do not know whether the health department of St. Louis has ever examined any of the wells located in the city, but even if they had, I should not feel certain as to the results of such examination, because in the present state of the art, as I stated this morning, it is often impossible to tell by ordinary methods of examination whether a well is or is not safe for drinking purposes.

2364 If the excreta of typhoid fever should be placed in a privy vault, no man knows how long it would have to remain there before it would lose its infection. I believe it might be days, weeks or years.

2365 Ordinarily a privy vault does not closely resemble a septic tank, because it is a mass of tolerably solid material, while a septic tank is essentially standing or stagnant sewage. That is to say, something very much more dilute. At the same time, some privy vaults are undoubtedly septic tanks, but as to septic tanks, while I believe that pathogenic germs are relatively quickly destroyed, we are not yet in possession of sufficient evidence to enable us to speak with entire precision on that head. I do believe that under some circumstances the typhoid excreta in a septic privy vault might be disinfected and under slightly different conditions, might not; but the ordinary privy vault is not in my judgment, a good septic tank. If the contents of such a vault should be placed where the same could get into a stream, it would contaminate the stream, both by way of pollution and infection.

2368 We attributed the cause of typhoid fever in Chicago in 1892, from the investigation I made, to the water supply.

2369 (Witness reads from his report of 1892.)

2370 The newspapers differed with us as to what was the cause of the polluted water supply at that time.

2371 If I remember right, they further quoted some of the city officials who made statements that the water supply of Chicago was pure and unadulterated. My paper was read before the American Statistical Association on January 22, 1892.

Q. Assuming that the water supply of Chicago was contaminated by the sewage emptying into the lake and this sewage was what caused the prevalence of typhoid fever in Chicago, would the elimination of all that sewage from Lake Michigan cause, in your judgment, a reduction of typhoid in the city of Chicago?

A. I should certainly expect it to do so. If the sewage of Chicago did not enter the lake, I should certainly not consider the lake water seriously contaminated water.

2372 In view of the fact that steamers are constantly passing in and out of the mouth of the Chicago river and that the lake apparently is used by numerous fishermen and pleasure seekers and that in times of extraordinary rain-fall the Chicago river may even today have its current reversed for a time, I cannot say that I should consider the water of Lake Michigan within four miles of the shore on the lake front of Chicago as a perfectly wholesome and suitable material for drinking purposes under the conditions assumed. I do not know of any large city in the country whose water supply rises to the perfect standard fixed by sanitarians.

Q. Do you know of any city in the country that will have a better water supply than the city of Chicago when the sewage of the Sanitary District is completely eliminated from Lake Michigan?

A. Yes, I think so. I think that the water supply of New York is better than that of Chicago would be under those circumstances, or would be likely to be later on. I think that the water supply of Boston is another example.

2373 If the sewage system of Chicago when completed will be a complete elimination of the sewage of Chicago from Lake Michigan into the Drainage canal, that ought to be followed by material reduction in the typhoid fever death rate. I should expect that it would be. As the reduction of typhoid takes place, the danger from the sewage of Chicago going into the lake will be thereby decreased. The elimination by that process will tend gradually to purify and improve the water conditions of Chicago so far as that element is concerned. That in turn will eliminate to a large extent, the infection of the Illinois river but if the rate fell off one-half and the total number of cases continued the same, owing to the growth of the city, or by any other means, then the quantity of typhoid material put in the sewage would remain the same.

2374 I assume that Chicago is going to be one of the greatest cities in the world, but I assume also that under the conditions mentioned, the typhoid fever death rate will fall off very largely. Yet, the total amount of typhoid material thrown into the Drainage canal may even get bigger than it is at present. As I recall the river when I examined it, I should say that some parts of the Chicago river at times were undoubtedly in such a condition as to be likely to abbreviate the life of pathogenic germs.

2377 Typhoid germs are found in various parts of the human body, especially in the spleen and alimentary canal. I believe that there are so-called cases of typhoid fever in the lower animals, but these are, to say the least, uncertain and I cannot say that the existence of such well-defined germs has ever been made out. We therefore look to the human subject as the source of pollutions of water, sewage and the like, rather than to any of the lower animals. The sewage that enters the Illinois river at Peoria will purify itself within 25 or 50 miles, to a certain extent, but not to such an extent that I should consider the stream into which it is poured, fit for drinking purposes.

2378 In my direct examination I stated that if the water of Lake Michigan, considering the fact that the sewage from about a quarter of a million of people is discharged into the lake, was conducted through a conduit directly to Grafton, and that no other sewage from Chicago was conducted to Grafton, that such Lake Michigan water would be dangerous and unsafe to the citizens of St. Louis. I should say that the dilution would be enormous from Chicago; it would be enormous in Lake Michigan and would be still further increased in mixing with the Mississippi at Grafton.

2379 I am still of the opinion it would render the water supply of St. Louis dangerous and unsafe under the present conditions at the intake. As to whether it would be more dangerous than the water supply of St. Louis prior to the opening of the canal I cannot say. I have testified that I did not regard the Mississippi water, previous to the opening of the canal, as it arrived at the Chain of Rocks, as suitable for a modern city.

RE-DIRECT EXAMINATION by General Crow:

2381 During the years 1897, '08, '09, 1,001 deaths were reported on the watershed tributary to the intake tower of St. Louis. In Chicago during the same years, the total deaths reported were 1,115. The number of deaths reported on the watersheds tributary to the Missouri river for 1901 and 1902 were 1,144; for the same years in Chicago, 1,647.

2382 I do think there would be a material increase of cost in the proper management of filters at St. Louis by reason of the added pollution and infection from Chicago. This I state upon reflection, after having considered my testimony on cross-examination.

2383 The fact that Chicago had an epidemic in 1902 of typhoid fever and that such a thing is likely again to arise, the operation of filters in the hands of any competent person would require extraordinary and constant attention and skill at St. Louis and such things are costly. The increase in population in Chicago to three or four million people might necessitate double filtration at St. Louis. (Witness refers to future consequences that might arise by virtue of the increased population in Chicago.) When we consider that during each of the three-year periods referred to heretofore, I have been able to learn of only about 11,000 cases of typhoid in the cities on the watershed on which the intake is located and that I find there must have been about 16,000 cases in Chicago during the period of three years since the opening of the canal, it appears that the opening of the canal has more than doubled the probable number of typhoid fever cases in the urban communities on the watershed above the intake. Although Chicago is 358 miles distant from St. Louis, some of the cities on the Missouri and Mississippi watersheds are even farther away. When I consider all these facts, I cannot escape the conclusion that the opening of the Drainage canal was a very grave addition to the sanitary and financial burdens of the people of Missouri using the water of the Mississippi below Grafton.

MR. TODD: I move to strike out the answer as not responsive and is not proper on re-direct examination.

In my cross-examination, reference has been made to the dams in the Illinois river; the general effect of dams is to hold back the water and produce slack water basins and any checking of the flow and slowing down of the stream—other things being equal, favors sedimentation and the disappearance from the supernatant waters of infectious material. The carrying down of the germs and the detention of them in the sediment removed them from the moving water in the first place, and in the second place, by detaining them, gives them an opportunity to die out more or less. On the other hand, streams are subject to scouring more or less frequently, and the disappearance of infectious materials is not necessarily their destruction. A considerable increase in the flow of such a stream as the Illinois river must tend to favor the return to the supernatant stream or lake or pond of some of the materials which it had previously deposited.

2387 While there is undoubtedly a high value in sedimentation and storage of infectious materials and a tendency toward their permanent removal either mechanically or by death, I do not feel that the processes referred to are trustworthy means of sewage purification under such conditions as existed in the Illinois river.

2388 Although typhoid bacilli are very rarely found in running streams there are other bacilli that are transported by water and convey water-borne diseases and they are, for example, the cholera germ and the supposed germs of diarrhoea and dysentery. As to animals, while I do not know whether glanders has been found in water, still glanders is supposed to be conveyed from one horse to another by water. Anthrax has been supposed to be conveyed by water. There is every reason to suppose it might be so conveyed, because it is one of the hardest germs to kill, of all that we have. I dare say there is a record of anthrax being found in the Illinois by the State Board of Health, but I don't know.

2389 As it is so difficult to discover the typhoid bacilli in water, one must judge of their presence by the effects which the water produces on those who use it.

2391 As to the typhoid fever at Pittsburg, I did not mean to state in my cross-examination that it was caused by the typhoid fever epidemic at Oil City or at Johnstown. The condition in Pittsburg was rather like that in St. Louis today—a large amount of typhoid fever, rather than what I should call an epidemic. It was not due to any special epidemic in Oil City or Johnstown or in any any other community upon the watershed, because I could not find in any of these, such unusual occurrence of typhoid fever, but rather that the regular and steady occurrence of typhoid fever in many places on the watershed had each contributed its proportional share to the making up of the total in Pittsburg.

2392 (Witness reads from his report in regard to Pittsburg.) JUDGE JOHNS: I move to strike out the extract so read as irrelevant and incompetent.

2393 As I have already said, broadly speaking, people living on farms on a watershed, and away from the banks, generally take care of their wastes on their own farms.

2394 The fact that there were 19 deaths from typhoid fever in January, 1900, in St. Louis, which was a larger number than had happened in January for several years at least, in February, the number was 5, which was smaller than in 1897, 1898 or 1899, shows that the little outbreak at the end of 1899 (prior to opening of canal)—whatever it might have been due to, had spent itself, while the occurrence of 16 deaths in March, 1900, has been, I believe properly attributed by Dr. Ravold, to the opening of the Drainage canal on January 17, 1900. At least a part of that increase may have come and probably did come from that source. On the other hand, the deaths in the next month fell off again to four, which was lower than during the two previous years, so that it is not easy to be absolutely sure that the number 16 did really come to any great extent from the first arrival of the material held in the Drainage canal. I may add that it is only by taking these things in a large way and for considerable periods that any safe conclusion can, in my judgment, be drawn. Boardly speaking, I do not think that after sewage which is infected with bacilli of water-borne diseases, is placed in running water, there is any absolute safety in using that water for drinking purposes within a month's time.

2395 I have been looking over what I said this morning, or parts of it, and I find that in answering the next question to the last, I contradicted myself and I desire to put myself right on the matter. (This question and answer related to the cause of typhoid fever in St. Louis in 1900.)

2396 What I intended to say was this, that there is evidence that the outbreak at the end of 1899 reached over into 1900, as is seen in the fact that there were 19 deaths in January in St. Louis, from typhoid fever, a larger number than had occurred in that month for several years previous. It is very clear that the outbreak referred to had spent itself in February, for the deaths in that month were lower than in any of the three years preceding. In March the number rises again to 16, being larger than for several years before in that month. It might be that some epidemiologists—in fact, I should myself have suspected, if I had no other explanation of the fact, that these 16 deaths meant a recrudesence of the previous outbreak. Fortunately, however, we have a simpler explanation in the fact that the Chicago Drainage canal was opened on January 17, 1900, and it is in evidence, I believe that not long after a mass of black and dirty water arrived at the intake of the St. Louis waterworks, which was believed to have come directly from the Chicago Drainage canal. In view of this evidence, I regard the excess in March, or at any rate, the larger part of it, as due not to a recrudesence of the outbreak at the end of 1899, but to the pollution of the St. Louis water supply by material arriving from Chicago. This conclusion was reached, I believe, or a similar conclusion by Dr. Ravold, who, as it seems to me, very properly attributed the greater part of the excess in this month to the cause described.

2397 (Objected to by Mr. Todd.)

In April on the other hand, the number was again low, which goes to show that the cause which operated, or the cause of the deaths in March, was apparently absent, or at least very slight. In matters of this kind, we must take the statistics in a broad way and cover considerable periods of time, if we wish to be absolutely sure. Mr. Johns in cross-examining me, stated as an assumed fact that the population along the banks of the Illinois river produced a larger number of typhoid cases than populations not upon the river.

2398 The increased flow from the Drainage canal would obviously move forward the typhoid dejecta from this pop-

ulation more rapidly and quicken somewhat its delivery into the Mississippi river and the time of its arrival at the intake. Judging chiefly by the typhoid fever death rate in St. Louis during the years 1895, '96, '97, '98, '99, the sanitary condition of the water supply as actually delivered to the citizens during those years, was good. Based on the typhoid death rate since January 1, 1900, and assuming that there has been no change in the treatment of the water supply of St. Louis, the death rate has been such as to place the said water supply under the gravest suspicion of contamination, to tend to remove it from the class of cities having good water supplies and to place it in or
2399 near the class having polluted water supplies.

RE-CROSS EXAMINATION by Judge Johns:

Since giving my answer to Mr. Hamlin stating that the expense of filtration of the waters of the St. Louis supply would probably be the same whether the waters of the Illinois River were added or not, I have been giving that question considerable thought. What I meant to convey was that in view of the infection that I believe comes from the Illinois iver, we should have to have here a more careful and expensive system than we would have had to have without it.

2400 Broadly speaking, I should say that for the last ten years the water supply of St. Louis ought to have been filtered. If they ought to have a filter, it ought to be managed with great care and by good men, in any event.

2401 Assuming that the waters of the Illinois River which entered the intake would be as one is to sixteen, I would not know what the additional expense would be in arder to filter this Illinois water.

2403 I don't think any one ever made a filter for non-pathogenic germs and I should not think it was necessary, broadly speaking, to make a differently constructed filter with reference to non-pathogenic than for pathogenic germs. If the Missouri River has twice as many germs in number as the Illinois River and the Mississippi River combined, at the intake, it would be necessary in filtering against the entrance of these rms, to have very great care taken of the waters from the Missouri River.

05 You have got to construct filters with reference to conditions.

Q. Well, the conditions being assumed that the Missouri ver as to all kinds of bacteria combined and all kinds of solids suspension and solids in solution, is much worse than the aters of the Mississippi and the Illinois arriving at the intake the waters leading to the filter, it would be necessary in the eparation of that filter, to recognize the condition of the Misuri River, wouldn't it, and arrange to filter the waters of the issouri, combined with the other two?

A. Certainly, if that were the fact and if that were the hole fact, but I don't understand that it is.

Q. I am assuming the questions and am responsible for em. If that were the fact then in constructing the filter you ould construct it with reference to the very large predominice of the Missouri water requiring filtration, wouldn't you?

A. Certainly, if that were the fact and it was so all the time.

06 Q. Suppose that a filter was constructed which would at all times and under all circumstances, filter successlly the waters of the Missouri river, wouldn't that filter at all nes and under all circumstances filter with equal success, the aters of the Illinois?

A. I don't know. I should have to know more about the emical composition of the waters of the two rivers, at differt seasons and times. Not being sufficiently familiar with e general character of the waters to form an opinion, I should be unable to answer that question.

09 I do not know whether or not the total increase in population of Chicago upon the basis of the census of 1890 d the census of 1900 is equal to, or greater than the total inease in population of all the other cities in the watershed of e three rivers combined, the Mississippi, Missouri and Illiis. I took into consideration, in stating the future pollution

of the Mississippi river, not only the increased population in Chicago, but the increased population in the watershed. I intended to include in my remarks the idea that if the population along the banks of the Mississippi should increase, as I anticipate, and excluding the population of Chicago and its consequent sewage, there might in the future come a time at very low water, when the Mississippi would be almost a river of dilute sewage.

2410 (The same applies to the Missouri river.)

Q. In which case, it would be necessary for St. Louis to get its water from the Merrimac, or resort to double filtration?

A. No man can say, but something would have to be done —something serious.

Q. Do you not anticipate that at some time in the future all these things will be changed, and these communities will destroy their sewage at their point of origin?

A. I have often wondered about that and tried to imagine what was likely to happen. As I think I intimated in some part of my testimony, that has been the general line of human progress in the most civilized communities. In England, for example, they are paying more and more attention to the purification of the sewage before they put it into streams, and similar processes are going on today in the older communities of this country. I was told that when the canal was opened in 1900 that the waters of the Illinois were very high and that there was an appearance of black water at the intake of the St. Louis waterworks.

2411 I understood that at that time the Missouri was low or at any rate, that the conditions were such that the mixed Illinois and Mississippi found ready access to the intake. I know that the pumps at Bridgeport undoubtedly at times did lift considerable sewage into the Illinois and Michigan canal, but I have always regarded the Bridgeport pumps as an uncertain element in the matter. I have understood the purpose of putting the pumps at Bridgeport was to pump the sewage of

Chicago into the Illinois and Michigan canal from substantially the same area as is now drained by the Sanitary canal. I have made no special study of the point, but I should judge there would be a difference of a day or two in the flow of the Illinois before 1900, in January, and after that time, with reference to the arrival of the waters at its mouth at Grafton.

2412 I should not expect that, assuming the quantities of sewage to be the same, that those two days more of time in arriving at the mouth of the river at Grafton would so immensely purify the water that it would be innocuous. Assuming that the dangerous qualities were equal in the two, I should not expect it to be so immensely purified in that lapse of two days as to remove 30 per cent of its dangerous qualities. I should not assume that it would remove 10 per cent of the danger, because any such assumption would be contrary to the facts. I don't think that a difference of two days would make any very great difference in the degree of purification under the conditions assumed, or existing, because the two days would be so small a portion of the whole period that if, for instance, the sewage came down in ten days, two days more would not make any difference—certainly would not make very much difference—in the life of the germs.

2413 Q. Which one of two individuals, one on the lake front in Chicago, and one on the Illinois river below Joliet, immediately casting dejecta, one into the waters of Lake Michigan and the other into the waters of the Illinois, would be most dangerous to the health of the city of St. Louis, if both were typhoid infected persons?

A. I think other things being equal, the one at Joliet.

2414 I am not prepared to say that the household sewage of the river population of the Illinois river is not as dangerous to the waters of the intake tower at St. Louis as the dejecta of the supposed 3,000 fisherman on the lake front in Chicago is to Chicago. I have never denied or failed to believe that there must be a lot of people along the shores of the Illinois river who throw things into the river.

2415 I should say that the three years after the opening of the
canal show the greatest death rate from typhoid fever
for the following reasons: (1) Assuming that the same amount
of sewage from the same population was pumped in, in the old
way, through the old Illinois and Michigan canal; it was really
a very different sort of sewage. The conditions then existing
on the Chicago river were totally different to those that exist
today. At that time the Chicago river was a kind of sedimentation
basin, and it not infrequently ran in the opposite direction
to that which it now takes. It was for the most part a putrescent
stream, resembling more or less what we sometimes call
a septic tank. And also (2) because in certain places, owing
to these facts, there were opportunities for the dying out of
typhoid germs in that river or its branches, but thirdly, and
perhaps chiefly, because the sediment deposited, as I have indicated,
was from time to time belched out into the lake, as I
have said, so that the Chicago water supply was often worse
infected than it is today, indicating that the typhoid germs
which now very likely come down to St. Louis, at that
2416 time, if alive, went on into the lake much more freely and
more readily polluted the water supply of the city of
Chicago. To sum up, because the conditions in the Chicago
river were so different from those which exist there today, that
it is not, in my judgement, difficult to explain the facts. I have,
of course, thought a great deal about this question, and have
endeavored to give it the fairest possible consideration. It is
a perfectly natural question which you have asked me, and one
that occurred to me long ago, and I have met it to my own
satisfaction, studying all the conditions and remembering all
the circumstances, and I may say that I believe that the period
since the opening of the Drainage canal would be far more likely
to be the one showing high typhoid fever in St. Louis largely
because the typhoid germs formerly held back in the Chicago
river, where they either died or were washed out into the lake
by heavy rains from time to time, have since January 17, 1900,
for the most part, been sent down the Illinois river, and al-

though many of them no doubt have disappeared en route, at least for the time being, they have in greater or smaller numbers, nevertheless, survived at other times, and even at some times have reached the intake tower of the St. Louis waterworks and caused typhoid in St. Louis.

2417 I don't know what the average rate of flow per mile of the waters in the Illinois and Michigan canal was for 15 years prior to 1900. I don't know what the average rate of flow of the waters of the Drainage canal has been since its opening.

GARDNER STEWART WILLIAMS examined in chief by Attorney General Crow:

2418 Am Consulting Water Supply and Hydraulic Engineer and Professor of Experimental Hydraulics in Cornell University. The results of some of my investigations which were presented to the American Society of Civil Engineers during the past two years recently received the Normal Medal, awarded by that Society. (States his experience.)

2420 Generally speaking, we have a practically equipped channel and streams of water at Cornell, with which hydraulic experiments are made. We are able to produce on the actual scale on which they exist, a very large number of the structures which are met with in the ordinary streams of the United States. The apparatus and streams which we have there are used both in connection with construction and in the line of original investigation.

2421 The water supply of Chicago, viewed from a sanitary
standpoint is certainly the worst of any supply furnished
to a large city on the great lakes; in fact I doubt if there is a
supply of any of the smaller towns that has such a con-
2422 tinuous reputation for infection. The amount of human
feces daily delivered into the sewers of Chicago is in the
neighborhood of 4,400 cubic feet. That is, the solid human feces
aside from any liquid mixture—that would amount to about 150
tons every 24 hours. It amounts to something more than 50 per
ent of the suspended matter of Lockport, as appears from
analyses there.

2423 The water used to dilute the sewage of Chicago as it is
drawn through the Drainage canal is taken from Lake
Michigan near the mouth of the Chicago river, and therefore,
from immediately over those large beds of sewage deposits which
have been found by investigators to be from one to four feet
deep in some cases. Assuming then as I have stated, that the
water supplied through the intake of the Chicago water-
2424 works is the principal cause, or one of the principal
causes of the high typhoid death rate in Chicago, the
water used to dilute the sewage of Chicago and sent into the
canal would certainly be likely to carry typhoid infection into
the Illinois river. Speaking generally, I should consider that
the discharge of such an infected water as that which would
flow into the conduits from Lake Michigan, near the mouth of
the Chicago river, or along the lake front of Chicago into the
Mississippi river would be likely to carry disease and infection
into the Mississippi river at Grafton and would therefore be a
menace to the health of people using the water of the Mississippi
river below that point, for drinking purposes. Most emphatically, I do not consider the mixture of water and sewage discharged into the Des Plaines river at Lockport of such a character as to be safe for use for drinking purposes.

Q. How is the character of this liquid discharged into the Des Plaines river at Lockport, changed by the time it reaches Grafton on the Missisippi river?

A. It is changed by the dilution with the waters reaching the Des Plaines and the Illinois rivers from other sources, by the effects of sedimentation along the line of the stream and by the action of the vegetation along the same. There is no question that under the conditions which exist in those localities on the Illinois river near Joliet and Peoria, where slack water is found and where the current is slow, there would be a very extensive deposit of the suspended material in the water upon the bottom of the stream, at such times as the flow through these portions is low and of a uniform character. As the pressure of the water varies from top to bottom, a particle in order to settle to the bottom must be of sufficient weight to overcome the differences of pressure from layer to layer in the water.

2427 Consequently, the lighter particles in the water will be the last to be deposited and bacteria, which are of very nearly the same specific gravity as the water itself, will only be borne to the bottom when entangled with the heavier suspended matter which is finding its way to the bed of the stream. In other words, the mud will be deposited first and the lighter particles—the vegetable and animal particles later, if at all. Any condition which tended to change what is called the regimen of flow—that is, which causes a change in the velocities from the bottom to the top of the stream, will cause changes in the amount of deposition, and will also frequently lead to what is known as scouring. It is particularly likely to stir up the suspended matter in the layer of water next to the bottom which is in a very dry unstable condition, and to distribute that material which in the quiet portions of the stream would be largely made up of the vegetable and animal life in the water, back into the stream.

2429 It is not necessary to have a condition of flood waters to take up the suspended matter and move it down from behind a dam. A very small change in the stage of the river at low water time would make a very decided difference in the transportation of sedimentary matter.

2430 The passage of boats would have a very decided effect in stirring up the deposits along the bed of a stream. This was evidenced by our investigations in the St. Mary's river. The observations were made by means of current meters after a boat had passed.

2431 In times of flood, the particles of sedimentary deposits which would be first picked up would be those in the layers of water overlying the bed of the stream, or in other words, those that were last laid down.

2432 The lighter particles of the suspended matter in the water and the lighter particles of the matter lying actually on the bed of the stream. Winds are very likely to cause similar disturbances. It has been observed on the great lakes, particularly Lake Erie, that after heavy winds, the waters of the lake are charged with greatly increased numbers of bacteria. At times of flood or of the disturbance of waters, I should say that the bacteria would be much more likely to be re-suspended, and when re-suspended would be carried much farther than would the particles of mineral matter. The bacteria thus stirred up would be carried on down stream. They might be in part re-deposited somewhere in the course of the flow, but some of them would undoubtedly be carried for very long distances in the water and in the case of the Illinois river would be discharged into the Mississippi. Whether the germs of typhoid coming from sewers of Chicago and passing by way of the Drainage canal into the Des Plaines and Illinois rivers that might be deposited in the bed of these streams and remain there for considerable periods, would be entirely destroyed or not, would depend upon the length of time which the bacteria might remain deposited in the bed of the stream, but under such conditions as existed upon the Des Plaines and Illinois rivers, receiving the sewage of the city of Chicago, I see no reason to believe that germs deposited in the bottom of the stream would be destroyed under existing circumstances.

2434 I have made an estimate of the length of time required for the passage of water, under existing conditions, from Bear Trap dam at Lockport, to the mouth of the Illinois river, and it appears that we may expect the water to travel this distance under the different conditions existing in the stream, in from one to three weeks, speaking generally. I estimate that in 1900, during something over 300 days, water would have flowed from the Bear Trap dam to the mouth of the Illinois river in less than 15 days. The discharge into the Missisippi river at Grafton, of the Illinois river, after the latter has received the mixture of Chicago sewage and water at Lockport, tends to increase the pollution and infection of the water of the Mississippi river and render it less safe for use for drinking and general household purposes below the mouth of the Illinois. When the Mississippi is in flood and the flow of the Illinois not above normal, I consider it possible for the waters to become so mixed as to effect the quality of the water upon the Missouri shore of the Mississippi river.

2435 That brings us back to the question again of the distribution of velocities and the distribution of pressure * * * * we may perhaps place this in more popular language by saying that the swifter moving stream exerts a suction upon the water of the slower moving stream, which leads to the dissemination and mixing of the latter throughout the volume of the former. The mixture would occur to a more considerable extent when the Illinois river was in flood and the Mississippi low, by reason of the velocity of the Illinois river, the momentum of the particles delivered into the Mississippi would be such as to carry them well out into the stream. In fact, it is observed that when the Illinois river is in flood the waters do pass well out into the main stream of the Mississippi river. The backing up of the Mississippi water into the Illinois river would have the effect of producing a quite thorough mixture of the waters of the Illinois and so much of the Mississippi as backed up into the stream, and as the flow or effect of this water which had been stored in the Illinois, considering it as an estuary, as it came out of the Illinois, would have the same effect as a flood rising in the Illinois itself, and producing an effect of additional scour on the bottom of the stream, and carrying the water into the Mississippi, which then being flowing rapidly, would have the mixed water more generally disseminated throughout the main current than would be the case with the rising river. I am prepared to state positively that at times the waters of the Illinois river reach the intake of the St. Louis waterworks.

2437 Even supposing that all the disease germs and infectious matter in the diluted sewage of Chicago as it passes Lockport should be rendered inocuous, under such circumstances, I should consider that the discharge into the Illinois river of the quantity of water now delivered through the Drainage canal would be a menace to the health of the people of Missouri using the water for drinking purposes for the reason that this quantity of water added to the stream during the low water periods, tends to materially decrease the time required for the flow of the water from various points along the Illinois river where pollution and infection may be and are added to the stream and thereby increase the liability of such pollution and infection reaching the Mississippi river in condition to do injury and harm to the citizens of Missouri who may be using the water.

2438 Each year the water of the Chicago Drainage canal would probably arrive in the Mississippi river at the Chain of Rocks within ten days of the time that it passed over or through the Bear Trap dam.

In making this estimate I used the proper methods that are used by hydraulic engineers in estimating the flow of streams to the best of my ability. Considering the suspended matters in the diluted sewage at Lockport, the quantity of water flowing in the Drainage canal and in the Des Plaines, Illinois and Mississippi rivers, I find that during about seven months in the year, the dilution of the suspended matters in the diluted Chicago sewage delivered into the Des Plaines river at the Bear Trap dam, when the said sewage and water reach the Mississippi river at the Chain of Rocks, would be from one-half to one part per million and that in the case of very low water in the Mississippi, the dilution might be reduced so that the suspended matter would represent a dilution of only one and three-fourths parts per million.

2439 I mean that the ratio of the amount of suspended matter delivered into the Des Plaines river from the Chicago Drainage canal at Lockport, and the quantity of water flowing in the Mississippi river is as from five tenths to one part of the suspended matter, to one million parts of the water of the Mississippi river, and that in time of low water, this ratio may be one and three-fourths parts of the suspended matter to one million parts of the water of the Mississippi river. This is based upon the solids which are in suspension in the sewage at the Bear Trap dam, and has no bearing upon any substances which may be in solution and therefore not appearing as solids in suspension, in the analyses of the water. At Detroit in 1892 a similarly diluted mixture of suspended solids from sewage matter produced typhoid fever. (Gives a description of the Detroit epidemic. See pages 2442-3 in regard to conditions existing on St. Clair river and Lake St. Clair, as to depth of water, rate of flow, etc.)

2443 I think that ten days is a fair estimate of the time required for the water to travel from the place where this material was dumped to the intake of the Detroit waterworks.

JUDGE JOHNS: I move to exclude that answer and to exclude all testimony descriptive of Lake St. Clair and its waters.

2444 The period of incubation for typhoid fever may be as short as seven days, or it may require in the neighborhood of four weeks, but probably about 75 per cent of the cases will incubate in from 10 to 15 days of the time infection is taken. I have concluded that 12 days is a reasonable and proper period of incubation to be allowed in the study of typhoid epidemics.

2445 I found that making allowances for the time required for infection to come from the point at Port Huron where this material was discharged into the St. Clair river and allowing the average period of incubation and the ordinary time to elapse between the taking down of the patient and the occurrence of death, that the sum of such times agreed within 24 hours with the time which had elapsed from the deposit of the dredged material from Black river into the St. Clair river.

MR. TODD: I move to strike out the answer because the witness has not shown that he is in possession of facts of personal knowledge sufficient to make the answer that he has made.

JUDGE JOHNS: I move to strike out all the witness' testimony as irrelevant and incompetent.

2445-6 (Witness makes comparison of Detroit waters with those of the Illinois river.)

2447 The presence of infectious matter in the water of the Detroit river was indicated by a largely increased prevalence of typhoid fever in all the towns along the St. Clair and Detroit rivers which had public water supplies taken from the Detroit and St. Clair rivers.

2448 I have figured the dilution of the matter taken from the Black river and find that it ranged from a ratio of 55 of a part of dredged material to 1,000,000 parts of water, to 1.1 of dredged material to 1,000,000 parts of water. The materials dredged were composed of deposits of silt and sediment apparently coming from the sewers of Port Huron. In ordinary stages, I would state the range of dilution of the sewage matter of Chicago, from the Sanitary District of Chicago, in the waters of the Mississippi river flowing past the Chain of Rocks to be from .5 of a part of suspended matter to 1. part of suspended matter in one million parts of water.

2450 Port Huron had sewers in 1892 and they discharged into the Black river. There had been typhoid fever in Port Huron during September and October, 1891. (Objection by Mr. Todd.)

2451 This dredging and dumping was done in the Black and St. Clair rivers in 1892. It began April 16, and the work continued on through the year, but the dredging of the particularly infectious matter ended in a comparatively short time—it was a matter of a few weeks.

2452 JUDGE JOHNS: I object on the part of the State of Illinois to all the testimony with reference to the history of the epidemic at Detroit, as irrelevant and incompetent.

2453 The quantity of the dredged material dumped daily into the St. Clair river at Port Huron in 1892 varies in amount from two to five times the amount of human fecal matter that is delivered by the sewers of Chicago into the Chicago river and thence into the Drainage canal each day. (Objection by Mr. Todd and Judge Johns.)

2454 Made a thorough investigation of conditions in Detroit and failed to find any local cause for this epidemic or any cause other than this dredging of Black river at Port Huron.

MR. TODD: I move to strike out the answer for the reasons heretofore stated. There has been considerable dredging in the Detroit, Black and St. Clair rivers and in Lake St. Clair since 1892. This has always been accompanied by increased typhoid fever in Detroit.

JUDGE JOHNS: In order to save the necessity of objections to each question and answer as propounded, the State of Illinois now objects to all testimony to be elicited from this witness with regard to investigations either by himself or other persons, of the cause of typhoid fever, and in any other place than in St. Louis, arising from infection of the waters at the intake at St. Louis, caused by the inflow of drainage from the Drainage canal in Chicago, and insists that such testimony is neither competent nor relevant and desires that this objection shall stand to all such testimony from this witness.

Another instance where the disturbance and discharge of sediment from sewers into a running stream has caused typhoid fever among the users of the water of such a stream is that of Grand Forks, North Dakota. The main sewer of Crookston, Minnesota, became damaged so that it failed to discharge the material delivered into it. Temporary repairs were made and a small connection was made around the break which carried off a portion of the liquid matter of the sewage and discharged it into the Red Lake river, which was the stream into which the sewage of Crookston was regularly discharged. In the fall of 1893 the sewer was repaired and on November 17, the sewerage system of Crookston was flushed of the accumulations which had gathered during the several months preceding. Sixty cases of typhoid had existed in Crookston in October and November, 1893. At the time of the flushing of these sewers into Red Lake river the river was frozen over. Grand Forks, North Dakota, is about 60 miles by river below Crookston. In November, 1893, there were reported in Grand Forks two cases of typhoid fever and no deaths. In December following the flushing of the sewers at Crookston on November 17, there were reported 230 cases of typhoid and 4 deaths; in January 712 cases and 52 deaths; February, 231 cases and 27 deaths; March, 46 cases and 11 deaths; April, 26 cases and 2 deaths; May, 1 case and no death.

2457 MR. TODD: I move to strike out the answer for the reason that witness has not shown that he had personal knowledge of the facts concerning which he has testified. (Witness again compares condition in St. Clair river with that in the Mississippi and Illinois as to flow and mixing.)

2458 Lake St. Clair might be and has been regarded as an ideal settling basin. When the Detroit waterworks was located, a commission of engineers, members of the United States engineer corps pointed out that in Lake St. Clair, Detroit was provided with a vast sedimentation basin which would add materially to the purity of the water drawn from the river at the point where it was proposed to take it. That report was made about 1860 or 1870.

2459 I am entirely satisfied that some of the infection in the sewage matter dredged in the spring of 1892 from Port Huron had remained or lived in that material for three or four months at least. I think it entirely probable that much of it had lived a very much longer time. The typhoid germs delivered into the St. Clair river at Port Huron must have lived a sufficient length of time to have traveled to Detroit, to have passed through the distribution system of the city, and to have been delivered to the consumers, and such time could not, in my opinion, have been less than eight or nine days, and in a great many cases, must have been as much as 12 or 15 days, or more.

2460 Typhoid infection usually comes into the water of streams through the sewage discharged into those streams. As a general proposition I most emphatically do not consider it safe to permit the discharge of human sewage in the streams of water which may thereafter be used as a source of water supply.

2461 It is my opinion that taking the conditions which I have found along the Drainage canal and streams which unite the sewers of Chicago to the intake, that typhoid infection or typhoid germs have at times come from Chicago to the intake of the St. Louis waterworks, that they may and will continue at times to do so under conditions which exist and which may be expected to exist in the streams aforesaid. The best criterion of the sanitary quality of a water supply that is being used by a community for domestic purposes, is the presence or absence among the users of such supply, of water-borne diseases, of which in this country, typhoid fever is at present the most important. The number of cases and deaths from typhoid fever in a community, I should consider the most important evidence to be adduced as bearing upon the sanitary quality of the water supply.

2462 The evidence afforded by the typhoid fever statistics of St. Louis for the period from 1895 to 1899 inclusive, indicates that while the water supply of St. Louis at this time was not ideal, it nevertheless would compare favorably with that of a very large number of our American cities. Considering the typhoid statistics since the beginning of 1900, it appears that up to near the end of January the water supply of St. Louis during the year 1900 must have been about as good as formerly, but that about that time there appears to have been considerable infection of the supply which has continued to increase from time to time since, with the result that the typhoid statistics show the probable infection of the supply during the year 1902 to have been nearly twice as great as existed on the average from 1895 to 1899 inclusive, and that the rank of the water supply of St. Louis has materially dropped, judged by the standard of sanitay purity. I have not found anything in the typhoid statistics for the cities on the Mississippi, Illinois and Missouri rivers outside of the sanitary district of Chicago that would account for this.

2463 Basing my opinion upon the facts brought to light in an extended examination of the conditions which seem to me likely to bear upon the question involved, it is my judgment that to the discharge of sewage by the sanitary district of Chicago into the Mississippi river, by means of the Chicago Drainage canal, the Des Plaines and the Illinois rivers, is attributable the major part of the increase in typhoid fever, revealed by the typhoid statistics of the city of St. Louis since the beginning of 1900, as compared with the period from 1895 to 1899 inclusive. The fact that the chemical analysis fails to show the presence of disease producing infection, is no evidence to an expert that such infection may not exist in the water in question.

2464 A chemical analysis is a valuable aid in that it may show the presence of substances which would be inimical to the health of persons using the water. If it fails to show anything of a deleterious character, it is not to be accepted as evidence of purity. If it does show the presence of substances which are recognized as connected with infectious material, then it is to be regarded as a valuable indication of the possibility of contamination.

2465 Chemical analysis made of the water of the River Dee in Scotland, were entirely unable to detect the presence of microbes, while in the bacterial analysis simultaneously made, the bacterial content of the water was shown to contain thousands of organisms in a cubic centimeter. Analyses of the water of the Detroit river were made by competent and experienced chemists in 1892, who were accustomed to making analyses of that water and they expressed themselves as entirely unable to detect in that water any indication of pol-

2466 lution. The water at Detroit at that time was clear.

2467 I consider that whenever chemical, microscopical or bacterial analyses of the water indicates the presence therein of substances which are known to be related to infectious matter, then it is proper to give to the evidence of those analyses, great weight in estimating the quality of that water and the expert should not recommend such water for use, speaking generally, until he is satisfied that the source of such organisms or such constituents or impurities, is such as to be unlikely to affect the sanitary quality of the water. On the other hand, it is not necessary for the expert to depend, or to require either a chemical or microscopical or bacteriological analysis of water to determine its pollution, if it is possible for him to see polluting matter flowing into it. Assuming that the numbers of bacilli coli communis in the waters of the Illinois river at Grafton are at intervals no greater than the numbers contained in it before the opening of the canal, I most certainly do not consider for that reason that said water is at all times no more dangerous for drinking purposes than before the opening of the Drainage canal.

2468 The germs of diphtheria, tetanus and anthrax have considerable length of existence in water. There have already occurred in St. Louis, cases of anthrax, one of which has been traced apparently to the water supply and the germ of anthrax is reported to have been found in the waters of the Illinois river. Should anthrax be present among cattle which are daily slaughtered in the Chicago stock yards and from them be transmitted by the discharges from the nostrils, mouths or bowels of those cattle, into the sewers of Chicago, there would be no question that the germs of anthrax might easily find a lodging in the people of Missouri with extremely fatal results.

2469 Should the sewage of Chicago become infected with anthrax there would be great danger of the occurrence of an epidemic of anthrax not only among the human inhabitants of Missouri, but also among the lower animals using the water.

Glanders is also transmitted through water and the same would apply to that disease.

2470 MR. TODD: I want to object to the question as to form and to strike it out as being based upon information and hearsay evidence.

Hog cholera is the nearest prototype of typhoid fever that is known among the lower animals. The bacilli of hog cholera are conveyed by water in the same manner as the bacilli of typhoid fever and coli communis, the three germs being very closely related. There is no doubt in my mind but what the cholera bacilli of hogs might be transmitted through the canal and the water-ways connecting the Mississippi river below the mouth of the Illinois.

2471 There is no doubt in my mind but what mud, silt and sewage matter under existing conditions may be removed from the bed of the Illinois river, the Drainage canal and the Des Plaines river into the Mississippi river and there deposited to remain for a greater or less time upon the bed and sides of such river. The volume of water added to the Des Plaines and Illinois river by the opening of the Drainage canal would unquestionably increase the quantity of such material so delivered because it has greatly increased the velocity of flow and has therefore prevented to a considerable extent the deposit of material which otherwise would have found its place upon the bottom of the stream.

2472 In the event of an epidemic of Asiatic cholera in Chicago under the conditions now existing in the waters between Chicago and the Chain of Rocks, through which the sewage of Chicago now flows, there is not only a possibility but probability and almost a certainty that the germs of the disease would be communicated or transmitted to the water supply of the city of St. Louis and the consumers thereof.

2473 If, with the knowledge of the existence of the conditions at Chicago and along the Drainage canal and the Des Plaines river and the Mississippi river, that are now known to me to exist, an expert should state that it is impossible for infec-

tious matter discharged by the sewers of Chicago to reach the Missouri shore of the Mississippi river, and the intake of the St. Louis waterworks at the Chain of Rocks, and to be a source of danger to the citizens of Missouri, residing on the Missouri shore of the Mississippi river and using the water therefrom for drinking purposes below the mouth of the Illinois river, and the citizens of St. Louis using the water supply drawn through the intake at the Chain of Rocks, I should say that he had thereby shown such lack of knowledge of the history of water-borne diseases, and the life and phenomena connected with their transmission and infection, as well as of the laws of flow of water in open channels, as to totally disqualify him as
2474 an expert upon the sanitary value or quality of a public water supply.

MR. TODD: I move to strike out the answer.

Considering the existing conditions in Chicago and the Sanitary District, the Drainage canal, the Illinois, Mississippi and Missouri rivers, I would, as an expert on water supplies, beyond reasonable doubt attribute the principal portion of the increase of typhoid in St. Louis since Jan. 17, 1900, to the infected sewage of the Sanitary District of Chicago. The most common method of sewage becoming infected with typhoid bacilli is by the discharge into sewers of the dejecta of typhoid fever patients. The most dangerous source of danger-producing infection in public water supplies of towns and cities in this country is the sewage of large communities.

2475 I have not any experience which would cause me to believe that any stream can be absolutely relied upon at all times to remove disease bearing germs such as typhoid bacilli, which may have been placed therein. (Witness testifies as to the effect on future generations of the discharge of Chicago sewage into the Illinois river and states that the menace to the health of St. Louis arising therefrom, will be much more tremendous and impending than exists at the present time, grave though the present condition be.)

2478 Based upon my past experience and knowledge, I would say the city of Chicago is today contributing considerably more than half of the entire sewage pollution which reaches the streams upon the water-sheds tributary to the Mississippi river above the Chain of Rocks. Upon examination of the population of cities of 4,000 inhabitants or more, resident upon the water-shed of the Mississippi river and its tributaries above the Chain of Rocks, exclusive of those residing in the Sanitary District of Chicago, and a comparison with the population of the said Sanitary District, contributing its sewage of the Chicago Drainage canal, I find that when the said Chicago Drainage canal was opened in January, 1900, there was added to the population previously existing in cities of 4,000 inhabitants or more, upon the water-shed of the Mississippi river, above the Chain of Rocks, a number of urban inhabitants amounting to over sixty per cent of those already there, and a number of sewage contributing inhabitants sufficient to more than double the number previously existing.

2479 I stated in my examination yesterday that the flow of water in low water stages in the Missouri would lessen as the years increase. This I attribute to the increase of population and the denudation of the forest areas.

2480 The amount of sedimentary matter carried by the Missouri itself will be reduced by reason of the reduction in flow in its upper tributaries and consequently its effect in producing precipitation of the bacteria in the mixed water will be deceased in even greater proportion than the decrease of percentage of Missouri river water at the intake.

2481 There has been an epidemic of typhoid at Ithaca, New York. The population is between eleven and twelve thousand with probably three thousand students. About half the deaths occurred among students. The water supply is taken from four sources. Cornell university takes its supply from Fall Creek. The public supply is furnished by a corporation known as the Ithaca Waterworks Company and obtained from two streams—Buttermilk creek and Six-mile creek.

2482 The epidemic broke out practically all over the town excepting upon the campus and in those portions where well water was used exclusively. An investigation revealed the fact that the epidemic was beyond question, primarily due to an infection of the water supply of either Buttermilk or Six-mile creek, or both. An examination of the specific cause of the outbreak showed that it was possible it might have come from several sources, but the most probable source of the bulk of the infection lay in the fecal discharges of a gang of workmen who were employed by one of the railroads in the construction of some culverts across one of the tributaries of Six-mile creek, some five or six miles above the intake of the waterworks.

2483 It is quite interesting in connection with this epidemic to see that there were continued re-infections of the water supply following successive freshets. I have investigated the water supply of Charlevoix, Michigan.

2485 During the warm season of 1897 the U. S. Revenue Cutter Rush, came into the harbor into Round Lake and anchored several hundred feet away from the intake of the waterworks, having on board a case of typhoid fever; the dejecta from the patient was discharged into the waters of Round Lake. Typhoid fever made its appearance in epidemic form in Charlevoix within two weeks of the appearance of the cutter.

2486 JUDGE JOHNS: I move to exclude the answer of the witness as to the disease in Ithaca and Charlevoix.

CROSS-EXAMINATION by Judge Johns:

2487 At the time of the epidemic of typhoid fever in 1892, I made no kind of investigation of it. I was not then practicing that branch of civil engineering which pertains to the erection of water supply systems. I began investigating it some time in the fall of 1895.

2489 In my investigation of the cause of that epidemic, I embraced territory for 100 miles up the Detroit river, Lake St. Clair, the St. Clair river and Lake Huron. I did not go

further because I regarded it as quite improbable that typhoid fever infection contributed by any of the communities tributary to the shores of Lake Huron above the mouth of the St.
2490 Clair river—those communities being in general small and very few and they not discharging sewage into the lake anyway—could possibly contribute a sufficient amount of contamination to mix itself with the water of such a body as Lake Huron and thereby produce any such serious infection as evidently had existed in the Detroit water supply at the time I had under consideration. When I commenced this investigation in 1895, so far as I recall, I had no knowledge of a case where the infection was attributed to a travel of more than thirty miles in a water supply.

2491 When I commenced the investigation in 1895 as to the cause of typhoid fever in Detroit in 1892, I think it may be considered that it was a new branch of water engineering and supplies, to me.

2492 The first I knew that the harbor of Port Huron had been dredged was at a meeting of the Detroit Engineering Society, held at the Hotel St. Clair in Detroit, sometime in 1896 or possibly 1897. I will correct my answer. It occurs to me that information did come to me in a letter from the city engineer of Port Huron a matter of a few weeks before the meeting of the Engineering Society. I am unable to state positively, but I think it was late in the fall, possibly in December, 1896. I ascertained the number of deaths from the mortuary records of the Detroit Board of Health. They were recorded consecutively as certificates were issued.

2493 All that I know positively as to the number of deaths in Detroit is from an inspection of the records and from the public reports of the local board of health and of the Michigan State Board of Health. I did not go to Port Huron in 1896 to investigate the dredging done there in 1891 and 1892. The records of deaths in Port Huron were obtained from the Michigan State Board of Health. They obtained them from the health officer of Port Huron. I did not know whether the report was correct or not.

2494 I do not know from the records, of the existence of typhoid fever in Port Huron prior to November, 1891, with the exception of two cases, which I recollect. The two cases I remember, my impression is they were cases and not deaths. Port Huron in 1891 had a population of nine or ten thousand.

2495 The population of St. Clair County in which Port Huron is situated in 1890 was 51,000. My impression was that there was no other town except Port Huron in that county, having a population of 4,000 or over. The towns with a population over 4,000, above Port Huron on the eastern side of the southern peninsula of Michigan, on the borders of the lake, are Bay City, West Bay City and Alpena. Alpena is pretty well up.

2496 Bay City and West Bay City together would have a population of 40,000. These towns are situated about three miles above the mouth of the Saginaw, which drains into Saginaw Bay, which is an arm of Lake Huron. St. Clair is between Port Huron and Detroit, on the shores of Lake St. Clair, with a population of 2,500 or 2,800. Marine City is also situated there, with a population not quite so large and Algonac which is nothing more than a village.

2498 There are flats or marshes in St. Clair Lake on both sides of the lake. There is considerable fishing in the delta at the upper end of the lake. The flats of Lake St. Clair are the delta of the St. Clair river and there are a number of summer resorts and club houses there.

2499 There is a considerable number of people visiting there, hunting and fishing so that there is a considerable number of constantly changing population on the lake during the summer season and the dejecta of these people goes directly into the water.

2500 You would be in Lake St. Clair in going a mile above the Detroit waterworks. In fact, I think in going half a mile. You would travel across Lake St. Clair about 24 miles to get to the St. Clair river and 30 miles by the St. Clair river to Port Huron. The St. Clair river is the outlet of Lake Huron, Lake Michigan, Lake Superior and all their bays and estuaries, on the travel of the water of these three lakes to the sea. At Port Huron the river is 1800 or perhaps 2000 feet wide in places. The St. Clair river is not subject to very great variations upon the six feet.

2501 I believe such variations as six feet have been recorded. These are not sudden and violent but very gradual. I am familiar with the data or measurements of discharge and velocity by which the cubic feet per second of the flow of the St. Clair river is ascertained. I obtained this data in conversations with men who were carrying on the work, who have been intimate acquaintances of mine for years, and an examination of the data of the discharges and the reading of their reports in their offices. The discharge varies from 180,000 to 200,000 cubic feet.

2502 If the discharge was 180,000 cubic feet per second, it would be over 15,000 million cubic feet for 24 hours. The discharge of the Mississippi river at St. Louis is between 180,000 to 200,000 cubic feet per second during the greater portion of the year. I obtained that from the reports of the Mississippi River Commission and of the United States Corps of Engineers.

2503 I found reports which indicated very much less amount at times and a very much greater amount at times. On August 5, 1881, the gauging of the Mississippi river at St. Louis shows 179,000 cubic feet per second.

2504 I do not find any for 1900. If there were any published I investigated them. I am not sure there were any as late as that. The same answer would apply to 1901. I am quite sure that I did not investigate any for 1902. I wish to correct my testimony and say that Port Huron had a population of about 18,000.

2505 I do not think I have sufficient familiarity with the city of Port Huron in 1890, 1891 or 1892, to make a guess as to the number of people whose sewage was discharged into the sewers of Port Huron. As to the volume or amount of such discharge, I have no kind of an idea, excepting that there were such discharges. It would be fair to estimate that 5,000 people discharged their household sewage into the sewers of Port Huron in 1890 and 1891, that would be between six and seven thousand cubic feet a year of solid matter.

2506 That would be about 230 to 250 cubic yards, or less than one-half the amount that was usually dredged in a day during the dredging of the Black river in 1892—substantially in round numbers, 40 cubic yards in two months. In the month of April, 1892, there was about 5,300 cubic yards dredged out of the Black river. That would be substantially 10,600 yards in April and May. This memorandum from which I read these figures was made by me from figures of some United States officer.

2507 I made this memorandum may be as early as 1897. I should assume 15,000 cubic yards would be a correct statement of the case and that 40 cubic yards might possibly be a fair estimate of the amount of solids in the household sewage coming from the bodies of persons using the sewers of Port Huron. I estimate the fecal and urine discharges of the people of Chicago who use the sewers of Chicago, which flow
2508 into the Drainage canal for one year, to be about 60,000
cubic yards, that would be 10,000 cubic yards for two months.

Q. Well, then, such solid discharges into the sewers of Chicago from the bodies of the inhabitants, which sewers enter into the canal are not five times as much as the entire amount dredged at Port Huron?

A. No, sir; they are not.

2509 The cubic feet of flow in the St. Clair and Mississippi rivers, assuming 180,000 cubic feet per second, would be 15,552 millions per day; for sixty days, being April and May, 1892, would be 933,120,000,000. In order to regularly, systematically and scientifically pollute a body of water flowing past Port Huron in the St. Clair river for one day of 24 hours, there would have to be 15,552 cubic feet of polluted matter to make one part in a million of pollution.

2510 If 15,000 cubic yards were regularly and systematically in a constant and regular flow put into the waters of the St. Clair river at Port Huron, such discharge would not pollute the water of the St. Clair river for more than 27 days, that is, at the rate of one part per million.

Q. What per cent of pollution of 933,120,000,000 cubic feet of water is 40 cubic yards of solid material, stated in parts per million?

A. About 108-10,000.

Q. 108-10,000 of one per cent?

A. 108-10,000 of one part per million.

Q. Do you want to be understood as saying on the basis of these figures, that if there was the dejecta of two typhoid patients put in some time about the first of April, 1892, in 40 cubic yards of solid sewage, from the bodies of people, in 933,122,000,000 cubic feet of water which would travel 57 miles, that that dejecta would pollute the entire body of water during any considerable portion of that time, or any portion of it?

2511 A. Considering the fact that the number of bacteria found in the excrement of typhoid patients has been on the average about 200,000 million per day, and that if these patients were sick with typhoid fever and recovered, they would each have been discharging that excrement so charged with infection, for a period of sixty days, and considering that there were assumed to be two patients, we find that there would have been probably discharged into the sewers of Port Huron, and from there possibly into Black river, and the material dredged therefrom, 24 million million bacteria, which would have been sufficient to have put about 27 bacteria into every cubic foot of water discharged under the conditions assumed, and it therefore seems to me possible that the infection might have been so distributed. During March, April and May in 1892, figuring on seven and a half gallons to a cubic foot, there were on an average 4,500,000 cubic feet of water pumped into the Detroit waterworks daily; assuming that the water in the St. Clair river passing Port Huron in a day was 15,552 millions, the per cent of it pumped into the Detroit waterworks would be three-hundredths of one per cent I think. 27 typhoid bacilli to a cubic foot of water would be about 4 individual, separated bacteria roughly speaking, to a gallon.

2512 I see no reason why some of these four bacteria in a gallon of water traveling 57 miles might not live and be virulent. In a laboratory experiment in 1888 it was shown that in ordinary potable waters the germs had been found alive after two weeks and it would not take them two weeks to go from Port Huron to Detroit under the circumstances assumed.

2513 I do not know whether these two people died of typhoid fever in Port Huron. I do not know whether these two cases recovered, nor whether the discharges from their bodies were cast into the sewers of Port Huron nor whether such discharges were destroyed or disinfected.

2514 Q. Without stating what you may have in your mind, do you wish to be understood as a sanitary expert, epidemiologist and sanitary engineer, that under the facts and figures elicited by your cross-examination, you are still of the opinion that typhoid fever resulted from the dredging of the harbor of Port Huron, and the mouth of the Black river in 1892?

A. I wish to be understood as saying that it is my belief that the typhoid fever in 1892 was very largely caused by the dredging of Black river in Port Huron during the same year.

2515 Assuming that 5,000 cubic feet of human discharges are put in the Drainage canal in Chicago in one month, there diluted with 300,000 cubic feet of water per minute, as it continuously flows into the Sanitary canal and then travels 357 miles down the Illinois and Mississippi rivers to the intake, and by the time it arrived at the intake was thoroughly mixed with the Mississippi river water, arriving continuously during the month and being diluted so that during the month it was contained in 933,120,000,000 cubic feet of water during the same month, understanding the word "pollute" to mean the addition to water of filth or infectious matter, or both, whether in large or small degree—I think that that sewage would pollute the intake waters at St. Louis.

2516 Considering the same facts and assuming that in this sewage there was dejecta from 75 persons who died of typhoid fever during that month, I wish to be understood that to whatever extent they might arrive at the intake, those bacilli in that dejecta would have a poisonous or deleterious effect on the waters of the intake, and I want to be understood as saying that they might arrive. I base that conclusion upon my knowledge of the life of the typhoid germ in water as determined experimentally; upon my knowledge of its transmission in the epidemic of Detroit, and epidemics other than Detroit; upon my knowledge of the conditions affecting the water supply of St. Louis previous to the opening of the Chicago Drainage canal; upon my knowledge of the conditions existing in and about St. Louis since the opening of the said Drainage canal, and the conditions existing in and about Chicago since the opening of the said Drainage canal, whence it appears clearly to my mind that there has as yet been found no other explanation sufficient to account for the increase now amounting to about 100 per cent in

2517 the number of annual typhoid deaths in the city of St. Louis, as compared with the annual number recorded during the five years previous to the opening of the Drainage canal, other than that the said infection has been received from Chicago throughout the Drainage canal, the Illinois river and the Mississippi river, and that therefore if much may come, it must necessarily follow that little may also come. I got my information about Crookston, Minnesota in the Engineering News and I believe it is also referred to in one of the health reports of Dakota.

2518 The report of this epidemic came to my attention along somewhere about 1897 or 1898. It was published in the Engineering News in 1893 or 1894. The author of the publication in the Engineering News was the city engineer of Grand Forks.

2519 There had been typhoid fever in Crookston. The supposition is that is where the typhoid epidemic of which we are talking, originated. I do not know how many cases occurred in one month, nor how many deaths there were from those sixty cases. I don't recollect whether I have seen a statement of the population of Crookston at the time the sewer became broken or clogged. I don't know what proportion of the people of Crookston have their household sewage emptied in the sewers nor whether any one of the supposed sixty cases had their dejecta thrown into the river. It was stated in the report that the city had sewers. Red Lake river at low water stage, its discharge has been shown to be 988 cubic feet per second. Grand Forks is 60 miles from Crookston. I do not know whether there were any cases of typhoid in Crookston prior to 1893 or 1892. I do not know whether there were any cases of typhoid fever there in January, February, March, April, May, June, July or August. I have no idea where the contagion came from that caused the
supposed cases at Crookston or whether that was a water-
2521 borne infection or not. I should not wish to make the
assumption that the infection which caused the disease
in Crookston was water-borne, without further knowledge of the
conditions existing there.

2526 I know that typhoid fever had been practically unknown in Charlevoix up to the time the United States Revenue Cutter came into the harbor. As to whether there had been or not, as a matter of fact I am not able to state positively. That boat remained in the harbor two or three days.

2527 The boat was in Round Lake and there was only a single case of typhoid on the boat. I have never heard whether or not the excretions of this typhoid patient were destroyed on board the boat or disinfected.

2528 Not knowing the usage on board U. S. boats in regard to the dejecta of people having contagious or infectious diseases, I presumed for the purpose of the investigation, that the United States officer allowed that stuff to be cast into the water.

2531 If 15,552,000,000 cubic feet each 24 hours passes into Lake St. Clair, as much water must go out through the Detroit river in order to maintain the stage of the water. It goes through with a velocity that I don't know that you would be warranted in saying that it was what would be dignified as a current.

2533 It would take a few hours for a body of water to flow from the head of the river at Detroit to the Detroit waterworks intake.

2534 I have not been up the Illinois river at a time of ordinary stage of water, nor at any stage of the water. I believe there are five dams in the river, but I never saw those dams in any stage of the river.

2535 Basins are created by those dams to a considerable extent. If a given dam on the Illinois river had a perpendicular heighth of eight feet above the pool below, in extreme low water it would back the water up the river a considerable distance. I am not certain that I have any information as to the fall of the Illinois river from Ottawa to Lacon. From Morris to Peoria the fall is 50 or 60 feet. From Peoria to Copperas creek dam, between 2 and 4 feet. The distance is about 30 miles. That is a very low grade. At certain stages that entire reach of river would be almost a sedimentation tank.

2536 I should say that at a stage of the river when the distance from the crest of Copperas creek dam to the surface of the pool below is six feet, the effect of Copperas creek dam would be to retard the flow of water above Peoria.

2537 When a dam ceases to be a submerged weir and is actually an effectual instrument in retarding the flow of the water above it, it does not necessarily aid in sedimentation and very frequently does not. The disturbance set up by the obstruction by the dam when the water runs over the dam, in causing change of direction in the flow of the current, stirs up particles on the bottom and tends to carry them over the dam.

2538 If the dam was 7 feet high, I would be willing to say it might extend back 50 feet. The passage of a stern-wheel steamer up the Illinois and the consequent agitation of the water would not contribute to the purification of that stream. Bacterial examinations for instance of the Niagara river above and below the falls have shown no change in the bacterial contents of the water at all and I doubt if any stirring up by boats would accomplish anywhere near the result that the flow over the falls and the stirring up afterwards would produce. I am unable to say if the waters of the Illinois river were continuously agitated for thirteen days that it would add to the purification of the water. My opinion of the value of aeration is that it has been greatly over-estimated. I have no definite idea as to the length that the typhoid bacillus might live in the sedimentation of the Illinois river.

2539 I am quite sure it would live more than 15 days. I am unable to cite a case of specific experiment and at the present moment do not recall one as to the length of time that any given lot of bacilli lived in sedimentation. (Witness states on what he bases his conclusion that the flow of water from Bear Trap dam to Grafton occurs in 15 days, for 300 days of the year.)

2543 At an average stage it would take the water a little less than twice as long; sometimes less than twice as long, to travel over the distance as it would in the case of flood, so that if floats were run over the Bear Trap dam to Grafton in the Illinois river at a stage of high water in 10½ days, I should say it would take possibly, 16, 17 or 18 days in traveling the same distance. I think an addition of 6 or 7 days in the flow of a stream like the Illinois would be a considerable time factor in its purification.

2544 There are cases on record where a bacteriological examination has determined whether the water was infected or

not. There are some reported on page 93, paragraph 18 of the report of the sanitary investigation of the Illinois river and its tributaries, prior to and after the opening of the Drainage canal, by Professors Zeit and Futterer. The statement is on record in a report of the Massachusetts State Board of Health that typhoid bacilli were found in the tap water as supplied from the running water at Lawrence, Mass. A bacteriological examination as a rule does not absolutely determine whether the water is infected, in fact, generally not. The ordinary assumption among sanitary engineers and experts is that if there are populous communities having their sewage and drainage thrown into running streams, that the streams are infected. I anticipate a very marked increase in population in the Missouri river
2545 valley and its tributaries as well as the valley of the Mississippi and Illinois rivers, and I might add that there is a probability of greater growth on the Mississippi and Missouri than there is in the valley of the Illinois, exclusive of Chicago, so that I think the amount of sewage pollution in each of these rivers—the Mississippi and the Missouri—is likely to increase much in the future.

Q. In their natural state, considering the future, the untreated waters of the Missouri river will be necessarily a menace to the inhabitants of St. Louis as the waters came into the intake, would they not?

A. I shouldn't think that the waters of the Missouri river in their natural state, either in the present, past or
2546 future, would be a menace, but if you mean with the growth of population upon the Missouri watershed, it would contribute additional infection to the Missouri river and cause it to become less healthful and less safe as a water supply, I am perfectly frank to answer, yes. That answer would also apply to the waters of the Mississippi. I can hardly conceive that in the distant future in a stage of very low water, that the Missouri river would become substantially a stream of liquid

sewage. I could conceive that as to the Mississippi a little more readily. This would not depend entirely upon the supposed and anticipated increase of sewage, but upon other considerations—the decrease of the flow of the streams themselves, for one. From the decrease of the flow and the increase in the population, the waters of both of these rivers would be dangerous for ordinary domestic purposes to the inhabitants of the state of Missouri on her banks.

Q. Are there other persons, sanitary engineers, expert in water supplies in this country, who are as familiar with the subject as yourself?

A. I think there are not very many.

Q. About how many?

MR. JEFFRIES: I object to the question as being incompetent, irrelevant and immaterial.

A. At the present moment, I do not think of any whose judgment I would take in preference to my own, or whose judgment I would advise a client to take in preference to my own.

2547 Assuming a certain number of cases of typhoid fever at St. Charles, Missouri and an equal number of cases at Kansas City, Missouri, and consequent typhoid fever in St. Louis, I would attribute the typhoid fever in St. Louis to both St. Charles and Kansas City. Of course I assume that the typhoid occurred in St. Louis at a proper time after the appearance of the other to permit of the connection. Assuming typhoid fever in St. Charles and Omaha and in St. Louis. I would attribute the St. Louis typhoid to both cities. Assuming typhoid at St. Charles and an equal number of cases at Helena, Mont., I would attribute the typhoid in St. Louis to both places.

2548 Assuming 50 cases of typhoid fever at Helena, Mont., and no other possible source in the Missouri river of infection of its waters from typhoid at that time, and that the waters from Helena, Mont., arrived at the intake and that in a proper time after that, there occurred in St. Louis an increase in typhoid fever, on the hypothesis stated, I should not want to attribute a very large part or more than a very small part of the increase of typhoid fever in St. Louis to the typhoid fever cases at Helena. The life of the typhoid bacilli in streams, is rather a question of time and distance, and as a general proposition I would say that it is my present opinion that there is no stream of water on the surface of the earth flowing in natural channels, that is long enough to warrant the absolute assurance that a typhoid germ might not live from one end of it to the other.

2549 If there were typhoid germs cast into the waters of the Mississippi at St. Paul, I think it is possible to a certain degree that these typhoid germs might arrive at New Orleans and infect the water supply of New Orleans. That is, I think it is possible that some of them might arrive. I would not want to be understood as saying that they would all arrive. One instance in which scientists in water supply have determined to their own satisfaction that the typhoid bacillus has lived in running streams for a distance of over 150 miles is the instance of the pollution of the St. Louis supply by the drainage of the city of Chicago. The pollution of some of the cities on the Merrimac river I believe are traced to distances as great as that. The pollution of the Connecticut river similarly and of the Hudson river.

2550 I am not prepared to make a specific statement that the infection of water in the Hudson river at a given point was caused by similar infection of the Hudson river 150 miles above, but a statement was made to me not very long ago that such was the case, by a gentleman who had made some investigation along those lines. I know of no other instance where the pollution of one water supply or infection was caused by the infection of a water 300 miles above, outside of the case of Chicago and St. Louis that we are considering.

2551 I do not recall of having heard or knowing of an instance in which the infection of a water supply was attributed to an infection 250 miles above the place where the infection was found to exist. Cincinnati and Pittsburg is an instance where the distance would be about 200 miles or considerably farther apart than that,—somewhere around 300 miles I believe. I think I have seen a statement on what would be considered the authority of some kind of a scientific man that waters of Pittsburg infected the waters at the intake at Cincinnati. My impression is that it was the Board of Sanitary Engineers who were considering the water supply of Cincinnati. I think so, but as I am speaking from memory on that, I won't be positive about it.

CROSS EXAMINATION by Mr. Todd.

2553 In my direct examination I figured the period of time in regard to the Detroit epidemic from the deposit of infectious material in Lake St. Clair to the four deaths occurring in Detroit and stated that the time corresponded within 24 hours for the transmission, incubation and death. A man may contract typhoid fever and not die before two months or perhaps six months.

2554 There are no cases on record that I know of or that have come to my attention where they have died before the end of three or four days after contracting it. I figured the time that these four patients were sick or had been down with typhoid fever before they died, by my study of statistics, regardless of knowing whether those patients had been sick for two or three months prior to death or not.

2555 In my study as a sanitary engineer and epidemiologist I don't think I have enunciated and demonstrated any new principles. I should hardly want to claim that I had been the pioneer in any new departure of investigation in these sciences. I rather think this science of epidemiology and sanitary engineering as to water supply, has not been exhausted. I think there are persons in this country or elsewhere that have made more extensive investigations than myself. If such a person should draw different conclusions than those which I have drawn, unless they were possessed of other facts which are not known to me, I would certainly consider that they had made a mistake. I consider that in my investigations of the conditions existing between Chicago and St. Louis on the watershed of the Mississippi above the intake that I am in possession of all the facts possible and necessary in this investigation and sufficient to establish the certainty of my conclusions.

2556 If one who has made greater investigation and had broader experience in these sciences than I have and should be acquainted with all the facts with which I have been acquainted, should draw different conclusions, unless he had different information to that which I had, I would consider these conclusions were unwarranted and unworthy of acceptation. I cannot conceive of any different information that could be obtained that would change my conclusions. I do not consider my conclusions in this case as infallible.

2557 If during the years 1896, 1897, 1898 and 1899 there existed upon the watersheds of the Mississippi, Illinois and Missouri rivers typhoid fever that resulted in the death of from 300 to 375 people annually, the presence of such cases would undoubtedly render the water supply of St. Louis unsafe and dangerous for domestic use. For even though the water was treated by what we know to be, and what analysis has shown was an inefficient method of treatment, the typhoid fever death rate and number of cases of death in St. Louis apparently traced to water infection is greater than should exist attributable to a good water supply. Had I been sanitary engineer of the water supply of St. Louis during those years, I should certainly not have recommended this water as a safe water. I should not have advised the people to drink it without further treatment by boiling, filtration or some treatment that would be sure of certainly reducing the possibility of infection from it. Boiling would add very much to the safety of the water. If the water were boiled now, I would consider it would be a safe water.

2558 Q. Is there any way known to sanitary science or epidemiology which can tell or demonstrate that the increased typhoid in St. Louis in 1900, 1901 and 1902, did not come from any one of the cities whose sewage emptied into the Mississippi river above the intake on the Mississippi?

A. There is no method that I am aware of that would enable one to demonstrate that no part of the infection came from any one of the cities in question.

2559 If there were a certain number of deaths from typhoid in Minneapolis and Kansas City each year during the years 1896-7-8-9, there is no means by which it would be possible to determine how much typhoid came to St. Louis from either one or that it did not come from both.

2560 It is not possible to establish the fact that it came from either one of the sources, that is, assuming that there was no existent history that would exclude either one or the other of these places as being the cause of typhoid in St. Louis. If conditions existing between Minneapolis and St. Louis and Kansas City and St. Louis were such as to be the cause of typhoid in St. Louis, there is no way known to my knowledge which can demonstrate whether the cause of the typhoid fever in St. Louis came from Kansas City and not Minneapolis, or from Minneapolis and not from Kansas City.

2561 I should not think it possible that notwithstanding the fact that conditions of that kind might exist as to those two places, that the contagion could come exclusively from Kansas City or Minneapolis. I think it would be impossible to make absolute proof either in the affifmative or negative. Now if we add to those conditions, all the conditions which actually exist along the watershed of the Mississippi river above the intake, I do not think it is possible then to say which one of these cities contributed the largest amount of typhoid existing in St. Louis for the years 1900-1-2. It seems to me that the proportionate share in the increase in typhoid fever in St. Louis from any of the upper cities can be demonstrated without an assumption. I could not say what proportion Minneapolis contributed.

I doubt that I can say what proportion any of the cities contributed outside of Chicago.

2562 Q. Can you show what Chicago contributed without assuming anything?

A. Not the absolute quantity.

Q. Any more than you could for Minneapolis?

A. I think so.

Q. Any more than you could for Kansas City?

A. Any more than for Kansas City, I think so.

Q. Any more than you can for any one of the number of cities, the typhoid statistics of which have been introduced in evidence here?

A. I think so.

Q. Is there a different rule applied by epidemiologists and sanitarians to the city of Chicago than would be applied to all or any of the other cities lying tributary to the water supply of St. Louis?

A. There is not, but different facts are in our possession in regard to the city of Chicago from those which exist in regard to the other cities on the watershed. We haven't got the facts as elaborately in regard to all the other cities as we have in regard to Chicago, but we have them sufficiently for all practical purposes, I think.

2563 The facts that I have about Chicago that I haven't about Peoria are that at a certain time, its sewage was added to the waters which supply St. Louis with its water supply. At that time the sewage at Peoria was being added to the water supply of St. Louis. I am not prepared at the present moment to give figures as to what was the difference as to the volume of sewage from Chicago entering the Des Plaines river previous to the opening of the Drainage canal and that which empties into the Des Plaines river now since its opening. The 4400 cubic feet that I have testified about of fecal discharges represented the solids in the fecal matter discharged into the sewers of Chicago which are tributary to the Chicago river and the

Drainage canal. Some of it undoubtedly enters the Drainage canal, but I do not know what proportion of it does.

2564 I could not say at the present moment positively whether the same territory that empties into the Chicago river the 1400 cubic feet of fecal mater is any different today from what that same territory was prior to the opening of the Drainage canal. I don't know how much or what proportion of that 1400 cubic feet was pumped into the Illinois & Michigan canal prior to Jan. 17, 1900. I am sure all of it was not pumped into the Illinois and Michigan canal prior to the opening of the Drainage canal. I don't know how much of it was. I don't know that I have any judgment at the present time based upon any accurate knowledge as to how much it was.

2565 I don't see how that influences the case any more than knowing the actual amount of infection that may have come from any other source that was continuous before the opening of the canal. I do not know the amount of infection that came from any other one source before the opening of the canal. I couldn't say how much sediment there was on the bottom of the Chicago river at present. I did not consider the sediment on the bottom of the Chicago river as a continually important factor at the opening of the canal. Today it has its importance, but it is not paramount.

2566 I examined the lake front in Chicago in 1892. I know that it is quite materially different in some respects at the present time. The conditions have been considerably improved.

2567 If it should appear that the Chicago river from the entrance to Robey street was of a depth of 26 feet in the channel, with the exception of the tunnels, and the condition has been created within the last three years, I do not think it would have any effect upon my conclusions in regard to the effect of sedimentation in the Chicago river. I don't know what effect the sewage pumped into the Illinois and Michigan canal prior to the opening of the Drainage canal had upon the water supply of St. Louis, nor how much typhoid in St. Louis could be attributed to it. I think it is safe to state now that the major part of the increase in typhoid fever in St. Louis is due to the sewage discharged through the Drainage canal. By major part, I mean considerably more than half.

2568 I should say that in St. Louis the cases probably increase to about the same extent or the same proportion as the deaths. The increase in deaths would be the most scientific way to consider the question of typhoid. If I have both the deaths and the cases, I say that the deaths are the better criterion because a man never dies but once and under the law, a record of his death is bound to be made somewhere, whereas a man may be sick of typhoid and no record appear, so that records of cases are always deficient. A man frequently has been acused of dying of typhoid, when as a matter of fact he did not have it, but there have been other cases where he died of other causes and they thought he had typhoid.

2569 To a moderate extent, it leaves the whole situation in doubt, but considering these things from a broad practical standpoint they will balance up in a period of years.

Q. If a man has typhoid fever and does not know it, why should the epidemiologist assume the fact that he has it when there is no evidence?

A. The epidemiologist does not assume the fact that he has it.

2570 Q. Assume that 160 deaths occurred in 1900 as against 198 in 1901, would that be evidence that typhoid had increased in St. Louis when the facts are that the number of cases decreased?

A. I should never base concluusions in a typhoid epidemic on the number of cases which are reported, for reasons already stated, and there is no question that an increase from 160 deaths to 198 deaths shows an increase of typhoid in the city. There is no question that the mortality in typhoid is affected by the skill of the physician, the care of the nursing and attendants, and so on; the asumption is that we are able to handle it better than before and I should say that the probability was that less people would have died of typhoid fever out of the same number of cases, in 1901 than would have died of it in 1900.

Q. Now if we assume that the number of cases, as is illustrated upon the chart that is already in evidence, is true, and that those cases started in 1896 with 291; 1897, 433; 1898, 426; 1899, 908; 1900, 1213; 1901, 1101; 1902, 1112, would you say, as an expert sanitarian, that the typhoid conditions existing in St. Louis for 1900 and 1901 and 1902 were attributed to the Drainage canal of Chicago and not to the same causes which created the uniform increase in typhoid fever from 1896 up to 1899?

2571 Assuming that the figures given are correct, I consider that the records of cases in the city of St. Louis in regard to typhoid prove nothing except that all of the cases were not reported in the earlier years and are not reported now. Assuming that the number of cases which you have stated in your question from 1896 to 1902 were deaths, I would attribute the gradual increase of typhoid fever in St. Louis during that period to gradually increased infection from somewhere. Where from I do not know. I would have to investigate the matter to see. Inasmuch as the condition assumed is contrary to the fact, I have not taken the trouble to investigate it. Supposing that in this number of cases none of them died, that by the best scientific knowledge of today, these cases were ascertained to be typhoid fever, and included all the typhoid in St. Louis, I could not say to what I would attribute the gradual increase of the number of cases from 1896 to 1902 without making a study of the conditions with such facts in view.

2573 In my consideration of this question, I took into consideration the sewage from Peoria. I don't know what the amount of sewage is that enters the Illinois river from Peoria. I do not know how many cattle are fed at Peoria. I could only make a guess. I know that Peoria is a place where cattle are very extensively fed. I have not particularly investigated the character of the sewage that comes into the river at Peoria. There is some difference in the sewage from distilleries and slaughter houses and the sewage from glucose factories. There would likely be acids discharged into the river from a large glucose factory. I do not know in what quantities. It would be likely that acids would be discharged into a river from distilleries.

2574 The effect of the discharge of acids in a stream the size of the Illinois from large distilleries and glucose factories at Peoria upon the life of the typhoid bacillus would depend very much upon the alkalinity of the water in the first place. Under some conditions it might tend to prolong it; under other conditions it might tend to decrease the life of the bacillus. I have not personally made any experiments under those assumed conditions. I am not aware of any one, at the present moment, who has made experiments with the typhoid bacillus in water impregnated with the sewage discharged from a distillery or glucose factory. I am not able to say positively whether that discharge would tend to increase or decrease the life of the typhoid bacillus. It might do either.

Q. Then if you are not able to say whether it would or it would not, can you say whether or not a typhoid bacillus on his journey from Chicago to St. Louis coming in contact with the sewage laden water at Peoria from the distilleries and glucose factories, would be able to live the journey?

A. I cannot say whether a specific typhoid bacillus would or would not be able to live under the circumstances assumed.

Q. Can you say whether a whole tourist excursion of those bacilli would live or not?

2575 A. I think it is entirely probable that some of them might squeeze through. I base my doctrine of probability, in the absence of any specific knowledge as to whether the individual bacillus would live in a medium of that character, upon the fact, which is very evident to my mind, that certain typhoid bacilli started from Chicago have lived, passed through the Illinois river and infected the water supply of

St. Louis and produced typhoid fever in those who have used it. I think we have pretty nearly proved in this case that the typhoid bacillus that left Chicago arrived in St. Louis. I don't know that I want to say that by my own individual self I have proved it, but I think it has been proven. I don't think that anybody knows very much more about this subject than I do. The typhoid bacillus that leaves Chicago, in order to get into the intake tower of St. Louis, must pass by Peoria. I do not know how many distilleries empty their filth and sewage into the Illinois river at Peoria. I do not see that it is of any importance whether there is one, one hundred or one thousand in that case.

2576 Moderately, I have some knowledge of the character of the sewage that comes from a distillery. I should not expect a typhoid bacillus to live in that kind of sewage a great while. I have a moderate idea of the character of sewage that comes from a glucose factory. I could not say whether a typhoid bacillus will live in that medium any length of time.

Q. Have you ever been able to identify any bacillus of typhoid found in the Mississippi river above the intake as being indigenous to Chicago and not coming from the other towns located upon the watershed of the Mississippi river, above its intake, the Missouri and Illinois?

A. Certainly not, and it would be absolutely impossible to do so any more than it would be possible to determine from what source a potato came that you might find floating in the river.

Q. Would the fact that you found a potato floating in the river prove that it came from Chicago?

A. Certainly not.

2577 Have never known of anybody catching lockjaw from drinking the germs of tetanus. I believe it is not contended that people get it by taking it in through the alimentary canal.

2578 As to whether it would have any effect on the health of the man who drank it, would depend upon the condition of his intestines. It would affect him if he had a raw place in his throat due to a cold or something of that sort. Assuming that there should be typhoid fever in New Orleans and two months before, one case of typhoid fever appeared on a steamer in Lake Itasca—the source of the Mississippi—and there were no other cases of typhoid fever between that point and New Orleans, and no other source of infection, I am afraid I would have to attribute the cases in New Orleans to the case in Lake Itasca. These things do not originate of themselves.

2579 I don't think I ever heard of a case of anthrax in Chicago.

I am free to say that I have not heard of a case coming from Chicago. I regard the sewage of Chicago as a greater menace to the inhabitants of Missouri than the sewage discharged by St. Louis into the Mississippi river would be to those living south of St. Louis. Assuming that Chicago sewage should be cut off, the water of the Mississippi river on the Missouri side, after it had received the sewage discharge of St. Louis would be unfit water to drink. I do not know that there is any more liability of anthrax or hog cholera occurring in Chicago than in St. Louis. It is entirely possible that if they did get hog cholera along the southern border of Missouri, south of St. Louis along the Mississippi, that it would come from St. Louis more likely than Chicago. I should look in St. Louis for the source of infection before I looked in Chicago. I believe that Chicago is more likely to get Asiatic cholera than St. Louis in event of its coming to this country at all.

2581 In regard to the case of anthrax I spoke of, appearing in St. Louis, I think it was due to the water of the Mississippi. It was attributed to the water by the man who had the case,—a physician here in town by the name of A. Ravold. Dr. Ravold attributed it to the water as being the most probable source. The case referred to was that of a woman who was scrubbing a sink and got a piece of slate in her hand. It was proved to be a case of anthrax. Inquiries were made to ascertain the source, and it was impossible to ascertain that there had been anything in the neighborhood of the sink that might have communicated the germ; at least it was not ascertained that there had been, other than the water, and knowing that bacillus had already been found in 2582 the waters of the Illinois river, it is at least a moderately justifiable assumption to say that it may have come from the water, and in fact, very probably did. I would not say for a minute, from the history of the case as I got it, that the water is the only explanation. I could not say whether it was attributed to the water of the Illinois river. When I look into the future I should not be surprised to see an anthrax epidemic in Missouri, understanding that there has been an epidemic of it in Missouri in the last few years. I could not say whether that was before or since the opening of the canal.

2583 I have personally investigated four or five epidemics. There is no school in this country that I am aware of which graduates a student with the degree of epidemiology.

RE-DIRECT EXAMINATION by General Crow.

I stated in answer to Judge Johns' question that I only found recorded in the official records two cases of typhoid fever in the year 1891 in Port Huron. They made no regular reports in Port Huron prior to 1893 I think. The two cases in 1891 seem to have been accidentally reported by somebody to the State Board of Health.

2584 There is no doubt that there were other cases in 1891 and prior to 1891 for several years, of typhoid fever in Port Huron. (Witness refers to report of State Board of Health, wherein reference is made to cases attributed to infection from Port Huron, in various years.)

2585 I estimate the least time, under conditions as they ordinarily exist, that water would flow from the point where the material dredged from the Black river in front of Port Huron, was dumped into St. Clair river, down to the intake of the waterworks of Detroit in 1892, would be somewhere in the neighborhood of 8 days. I think it is entirely possible that the water passing through the Illinois and Michigan canal in 1899 may have contributed somewhat to the typhoid in St. Louis. It very evidently did not contribute very largely because the typhoid in St. Louis was not excessive during those years. Moreover that amount of water passing into the Illinois and Michigan canal at Bridgeport was not sufficient to take care of anywhere nearly the sewage of Chicago.

2586 My impression is that some of the sewage of the Sanitary District still goes into the Illinois and Michigan canal. The elevation of the crest of the Copperas Creek Dam is given as 149 below the dam, and the Marseilles dam is given as 101, speaking of the river level of course.

2587 I should certainly consider, in determining whether or not Chicago sewage infected with typhoid germs would be likely to infect the water coming into the intake tower of the St. Louis waterworks, the time factor, that is, the time in which it would take water bearing infected sewage to flow. I should consider the time factor as one of the most important ones, in fact, next to the fact that infection was put in, I think I should consider the time it took to get somewhere else. When I stated to Mr. Todd that there are no facts that could be educed or come to my knowledge as to the prevalence of typhoid fever in the cities from which the complainant has introduced reports from the watershed tributary to the intake of the St. Louis waterworks, which would affect my judgment materially, I meant to convey by my answer that it did not seem to me possible that any facts could be educed which had not already been considered that would have a sufficient importance bearing upon the question, to change my opinion on a general proposition. I did not mean of course that my opinions were not subject to modification as additional facts might be brought out.

2588 I found from the statistics that the increase in typhoid fever in St. Louis has been regular and continuous since the 17th of January, 1900 and that up to the very last date of which we have a record, it shows it is continuously increasing. Any one in studying the conditions of nature is compelled to look for a cause for every effect, and if it were found that certain diseases were increasing the natural inference and proper assumption would be that there was a continuing and increasing cause for the existence of that disease, and if it should prove upon investigation that at a certain time this increase began, we should look at that time for the beginning of the cause which was leading to the increase.

RE-CROSS EXAMINATION by Mr. Todd.

In my investigations in regard to increase, I take into account the number of deaths. If the number of deaths should show an increase and the number of cases a decrease, or normal condition for 1901 and 1902, I would say, as I have stated alread, that I consider the death record decidedly more reliable than the record of cases. It is not a question of diagnosis; it is a question of report and a question of ascertaining the cases. If it should appear that the cases reported were the correct number of cases existing and the cases reported were correct diagnostications of the cases, I should consider that in all human probability the death standard would be the safer one to rely upon. If it were absolutely proved that the other were the case, that is that the number of cases represented all the cases, and that the probability of a correct diagnosis was the same as in the case of death, I should then give the record of cases an equal weight with the record of deaths.

2589 (Complainant offers a certified copy of typhoid fever death rates for the various years previously stated, at Kansas City, Missouri; St. Charles, Missouri; Council Bluffs, Iowa; St. Joseph, Missouri; Lincoln, Nebraska; Omaha, Nebraska; Chicago, Illinois; Davenport, Iowa; Moline, Illinois; Rock Island, Illinois; Galena, Illinois, and Warsaw, Illinois.)

(Complainant's exhibit 22 is withdrawn for correction, defendant's counsl consnting thereto.)

2602 GEORGE W. FULLER examined in chief by Attorney General Crow.

2603 Am sanitary expert. Professionally educated at Massachusetts Institute of Technology in Boston and University of Berlin, Germany. Have received an education as Bacteriologist, although that is not the particular branch of sanitary work which I gave the most attention to while at the Institute of Technology. That was the principal topic which I studied in Berlin. It was from the department of chemistry that I graduated at the Institute of Technology in Boston. In regard to the necessity and advisability of treating water supplies by artificial processes, I would say that I have given that matter special attention and with regard also to plans and specifications. (Witness states his further education, knowledge and experience.)

2606 Am familiar with the general features regarding the source and method of treatment of the water supply at St. Louis.

2608 As a general proposition, it is my judgment that the best index to the sanitary character of a public water supply is the mortality record from water-borne diseases in the community using the water supply in question, and especially the mortality statistics of typhoid fever. It is my experience that the typhoid fever mortality statistics are preferable to those of other water-borne diseases for a number of reasons, of which the principal ones, are the wide-spread nature and distribution of typhoid fever, its abundance in those communities having supplied to them sewage polluted waters; the well defined character of the disease, taking everything into consideration, and also the substantially large percentage of deaths to those who have the cases, that is, the percentage of deaths to cases is larger than in some other instances. From twenty-five to thirty thousand deaths result annually in the United States from typhoid fever. The number of cases occurring in this country annually I would place at more than a quarter of a million. It is my judgment that the water supplied to the citizens of St. Louis by the municipal water department during the years 1895

1899 inclusive, was what might be called a good sanitary water.

2609 I base that judgment on the fact that during the period mentioned the typhoid fever mortality statistics showed as low a rate, approximately speaking, as in the case of quite a number of other American cities having a pure or very nearly a pure water supply. The treatment of the water during that period consisted of settling the water in the basins at the Chain of Rocks. The result of this settling was to improve the water to a considerable degree as regards the elimination both of mud and bacteria, including those of a pathogenic nature, when such were present in the raw river water. There was substantially no change in the period for sedimentation during the years in question. Pathogenic bacteria, as used by me, include water-borne bacteria that might convey infectious diseases such as cholera and typhoid. In my judgment the raw Mississippi river water as it entered the intake during this period was a much less safe water from a sanitary standpoint than was the water after it had been treated in the settling basins. This was due, of course, to the elimination of bacteria of an injurious nature by the processes of sedimentation, and in which process the
2610 injurious bacteria subside—falling to the bottom of the
basin and from time to time are removed and thus prevented from passing on to the water delivered to consumers. These deposits are removed by artificial means once or more each year, by emptying the basins and flushing the mud into channels which conduct it to a sewer leading from the end of the basins to the river and down below, a considerable distance below the intake tower. I will classify this raw river water as it entered the Chain of Rocks intake tower during the years 1895 to 1899 inclusive as a suspicious water, meaning by that, not distinctly a good water, but one in which there is a liability of danger from time to time to those who drink it in its raw condition.

2611 The average annual deaths from typhoid fever from 1895 to 1899 inclusive is 112. During the three years, beginning with Jan., 1900, it is 196, showing an increase in the number of deaths of about 80%. Taking into consideration the differences in population, that is, the increasing population during that period, and expressing the typhoid fever deaths with reference to the number per 100,000 of population living there has been an increase during the past three years on an average, of about 60 per cent over the annual typhoid fever death rate per 100,000 population living, for the five years, 1895 to 1899 inclusive. Comparing the number of deaths from typhoid fever during these eight years, with reference to the total number of deaths from all causes, occurring in the city of St. Louis, and obtaining the percentage mortality from typhoid fever, the percentage increase for the last three years on an average as compared with the average percentage of mortality from typhoid fever during the five preceding years, is 73 per cent. I will further state that the average number of deaths from typhoid fever in St. Louis during the first five years under consideration was about 20.4 per 100,000 population living, and that this rate during the past three years, on an average, was about 32.3 on the same basis; that is, the average number of deaths per annum per 100,000 population living. In my judgment, the three methods of investigating and comparing typhoid fever statistics when considered together afford a proper and reasonable basis upon which to base conclusions with reference to typhoid fever statistics of the city for the reason that each throws light on the matter, but the data regarding the two last methods of comparison taken together are the fairest and best way.

2612 I should say in round nunmbers there has been an increase during the second period under consideration of about sixty to seventy per cent above the average rate in the earlier period mentioned. The number of deaths by months for

1903 up to and including Ma, clearly indicate an increase in typhoid fever in this city.

2613 The record of number of deaths from typhoid fever in St. Louis by months shows a continuance of these comparatively high figures to an unusual degree, showing that for this season of the year, there is an unusual prevalence of this disease in this city. I ascribe the increased mortality from typhoid fever in St. Louis since Jan., 1900, to an increased amount of infection in the water supply, and predicate this opinion on the practically uniform distribution of the homes or residences in which the typhoid deaths have occurred in St. Louis and the further fact that a careful examination of the other several possible sources of typhoid fever, show that no substantial portion of this increase may be explained in that way. I consider that the sanitary character of the public water supply delivered to the consumers in St. Louis has been less safe since Jan., 1900, than it was formerly. It is my judgment that this water as delivered to the consumers since Jan., 1900, cannot be classed as a good water. The treatment of the water since 1900 has been essentially the same as it was before. I consider that the sanitary character of the raw Mississippi water entering the intake tower of the St. Louis waterworks since Jan., 1900, has been distinctly and decidedly less safe than during the five preceding years.

2614 The principal source of dangerous impurities in public water supplies in raw condition is sewage pollution. I am familiar with the typhoid fever statistics in the larger center of population on the Mississippi watershed above the Chain of Rocks, excluding the Sanitary District of Chicago, since Jan., 1900. Taking the statistics upon this watershed area based upon the average number of deaths from typhoid fever per year, it is my judgment that there has not occurred on such area, any increase in the number of deaths sufficient to explain to a material degree the less safe condition of the Mississippi water at the intake tower during the last period as compared with the period from 1895 to 1899. In my judgment it is the Chicago Drainage canal discharging sewage and drainage containing filth and infection from Chicago which makes the water in its raw condition at the intake tower less safe than it was preceding Jan., 1900.

2615 There have been about 1647 deaths from typhoid fever in Chicago since Jan., 1900, and the infectious discharges from the persons sick and dying of typhoid fever, have to a very large degree been disposed of by their passage through the sewers to the Chicago river and the Chicago Drainage canal.

2616 In round numbers, I place the figure for those people who sewer directly into the Mississippi, its branches and tributaries above the St. Louis waterworks, exclusive of the Sanitary District, at about 2,700,000. This figure is based upon a separation, on an average of the sewage contributing population from the rural population by taking towns of 4,000 and over as representing those who have sewage systems and contribute sewage directly to the water courses. I include in this number the Missouri river and the Illinois river, exclusive of the Chicago Sanitary District, as well as the upper Mississippi. (Witness states reason for drawing the line at cities having population of 4,000.) In round numbers I estimate an increase of 60 per cent in population sewering into the Mississippi valley above St. Louis, due to the Chicago Drainage canal bringing sewage of Chicago into the Mississippi watershed. I place the figure as to the time required for the Chicago sewage to flow from Lockport to Grafton—291 miles—at from 10 to 25 days. The average time required, in my opinion, is about 15 to 18 days.

2618 I consider that the typhoid fever germs may and do continue to live for weeks and months in sewage polluted waters. Generally speaking, it is my opinion that there is not any very great difference in the life history of the germs of Asiatic cholera and typhoid fever. At times the flow of the drainage canal exceeds the flow of the Illinois river and there consequently results at times, a dilution of the Chicago sewage by the Illinois river, and at times, a dilution of the Illinois river by the contents of the drainage canal. Dilution at best does not destroy disease germs or infectious matters. Its effect is to minimize the danger to those who may drink of the water so diluted. One effect of the dilution existing in the Illinois river at low stages is to bring to Grafton more quickly than would otherwise be the case, injurious matter entering the Illinois river at points along the route of its flow and also entering the Illinois river from cities and towns located upon the tributaries of that river.

2619 The most significant feature of the ponds, dams and slack water stretches which are found in the Illinois river, is the low velocity of flow of the water, at times of low stages of the Illinois river. There are a good many days in the course of a year when these velocities at the places above referred to are so low that deposition takes place to a considerable degree, of the bacteria and other matters suspended in the water, and which to a large degree are derived from the contents of the Chicago drainage canal. The deposition of these bacteria including those of infectious diseases like typhoid fever, does not mean their permanent elimination and removal from the flowing water. The reason of this is that as they reach the bottom and lie upon the bed of the stream they are disturbed from time to time, due to changes in velocity of stream flow, such as caused by moderate rains, or by the passage of boats or the action of the wind and the like. The resulting disturbances cause the bacteria to leave the bed of the stream in which they may rest for some time, bringing about a return of those bacteria to the flowing water. In this way the germs of disease may pass from the Chicago drainage canal at Lockport to the mouth of the Illinois river at Grafton. I believe that typhoid fever germs disappearing from the flowing stream and becoming deposited in the bed of the river are able to live there for weeks or months. In my judgment, it is not only possible but probable that the water of the Illinois river, as it flows into the Mississippi may sometimes be richer in typhoid fever germs derived from the Sanitary District of Chicago and coming through the drainage canal, than was that portion of the water drawn from the drainage canal when it flowed over the Bear Trap dam. Such a condition of affairs made and at times probably does arise through the disturbance of the sediment lying upon the bed of the stream in places, which sediment may and undoubtedly does at times contain relatively large numbers of typhoid fever germs.

2620 As these typhoid fever germs are returned to the flowing stream from their position in the bed of the river, there is effected an accumulated result whereby at times at least the waters of the Illinois river flowing to Grafton may discharge the concentrated essence of the infection of the Chicago sewage by taking in the manner above described, portions of the infection coming from many days' flow of the drainage canal into the Illinois river. I know of no instance connected with public water supplies in which sedimentation is employed for the purification of sewage polluted water without any provision being made for the removal of the sedimented materials so that they will not re-enter the water as it leaves those basins. Without such means of removal, the object and purpose of the settling basins entirely fail. I do not believe that the conditions from Lockport to Grafton are sufficient at all times to prevent infected materials coming through the Chicago drainage canal and entering the Mississippi valley at Lockport, from reaching the Mississippi river at Grafton. It takes a fraction of one day in the ordinary stage of water for the Mississippi river to flow from Grafton to the Chain of Rocks—a distance of 29 miles.

2621 I do not believe that it is possible for the Illinois river water to flow by the Chain of Rocks without some of it ordinarily entering the Chain of Rocks intake tower.

Q. Mr. Fuller, in view of all the facts and conditions as you know them, do you or do you not consider that the sewage of the Chicago Sanitary District pollutes and infects the water of the Mississippi river along the Missouri shore, and especially at the Chain of Rocks intake tower of the St. Louis waterworks, to such an extent that it makes the Mississippi river water less safe for drinking and domestic purposes than it was before the opening of the Drainage canal?

JUDGE JOHNS: I object to the question as requiring the witness to determine what is to be ascertained by the United States Supreme Court on the trial.

A. It is my judgment that it does.

2622 Assuming that for the years 1900-1-2 there was no increase in the number of typhoid deaths on the watershed of the Mississippi river above the intake, exclusive of the Sanitary district of Chicago and that there were 1647 typhoid deaths for these three years in the city of Chicago, it is my judgment the typhoid infection coming from Chicago and passing through the Drainage canal by way of the Des Plaines and Illinois rivers to the intake tower had an influence on the typhoid fever death rate in St. Louis and that it is the cause of the principal portion of the increase during the past three years. Assuming that the population of the Chicago Sanitary District grows larger and that the amount of Lake Michigan water and sewage, etc., is correspondingly increased, I am of the opinion that the water at the intake tower would be rendered less safe than at the present time, due to the increased amount of infection entering the Mississippi watershed from Chicago, and to the

2623 shorter interval of time required for the passage of that sewage from Chicago to the intake tower. Such increased sewage caused by the increased population of Chicago would make the Illinois river and the Mississippi river at low water stages a much less safe water, generally speaking, than at the present time. It is quite possible that looking far enough into the future, this amount of pollution would become sufficient to exceed the oxygen and to make it in many ways resemble an open sewer—that is to say, it would be a stagnant pool resembling sewage rather than a live active water containing atmospheric oxygen. In my judgment the increased amount of infection coming into the Mississippi river from the city of Chicago's sewage at the present time makes an added responsibility as regards the treatment of that water, to make it perfectly safe and wholesome as supplied to the citizens of St. Louis. Such treatment of the water would involve, I think at the present time, more responsibility, and in a financial way, it would be shown by the greater expense of supervision of a filtration plant, and the added cost of supplies used in connection with the operation of filtration works, especially at times of low water.

2624 Looking into the future, there will be a time when single filtration will not be sufficient to produce a satisfactory quality of water at the Chain of Rocks excluding the water from the Sanitary District of Chicago. It is certain that the added infection from the Chicago sewage will hasten the day when single filtration at St. Louis will prove unsatisfactory and when it will be necessary to give attention either to double filtration or to other methods involving increased expense and increased responsibility.

CROSS EXAMINATION by Judge Johns:

My opinions are based on the assumption that the waters of the Illinois river are so polluted with the waters of the Drainage canal that they cannot purify themselves by the time they reach the intake at St. Louis, if they ever do, but with the idea that that degree of purification can take place at certain times—not at all times. There may be and may not be times in the Illinois river in the flow of the water from Bear Trap Dam to the intake tower at St. Louis when that water would free itself of infection, if any infection existed—I don't know.

2625 I doubt if there is any season of the year, any rate of flow or any stage in which it might happen. At times I certainly believe that infectious matter flowing from the sewers of Chicago into the Drainage canal will certainly arrive at the St. Louis intake. In order to provide against that contingency, some means of filtration or purification of the water should be adopted at St. Louis in order to get those particular germs out. It would be desirable to filter the water supply of St. Louis if it was received only from the Missouri, but it is not necessary in order to get a reasonably good water, as has been shown by the typhoid statistics and experience during 1895 to 1899. In order to get a thoroughly satisfactory water without liability of pollution from time to time, the waters at the intake, if consisting only of Missouri water, ought always to have been treated by other means than sedimentation, but it is also true that before 1900 they got a reasonably good water without filtration, but with the sedimentation.

2626 The typhoid fever in St. Louis prior to 1900 was due to a variety of causes. There is a residual number of typhoid deaths in American cities which are not ordinarily eliminated even with a pure water supply and they are still found in cities which are now provided with good water supplies. If the Illinois river and the city of Chicago did not exist, and the problem before the people of St. Louis now was what to do with their water, I think it ought to be treated in order to get a thoroughly satisfactory water, but as I have said, sedimentation from 1895 to 1899 gave them a reasonably good hygienic water. Sedimentation from 1895 to 1899 I would hardly say gave them a reasonably good water at all times. Judging from a sanitary standpoint, I should be inclined somewhat to doubt that sedimentation from 1870 to 1885 gave St. Louis a reasonably good water.

2627 The germ theory of disease became generally recognized in the United States among sanitary engineers in the late eighties. They have been learning all the while and are still learning. There is a possibility that in the future, the practice of filtration would have to be abandoned and sewage destroyed at its origin. Looking into the future, it is possible in low water that the Missouri river might become a stream of liquid sewage but that would be a long way off; it would be very highly sewage polluted no doubt. The same is true of the Mississippi.

2628 It is possible that the Illinois river might become a stench to the nostrils of the people, in which case there is a possibility of quadruple filtration being necessary if St. Louis persisted in taking its water from these rivers, but as I have stated it is also possible that other types of purification might be required in connection with filtration. I believe that typhoid bacilli entering the Drainage canal at Chicago not only may be, but are transmitted to the intake at St. Louis. It is a question of time interval and not distance which is the controlling factor in this proposition. Given a sufficient distance and a sufficient time in running water, and taking the proposition independent of dilution, there would be a very large reduction ultimately of typhoid bacilli, but whether those germs would be wiped off the face of the earth that way, it seems to me is very doubtful.

2629 If a stream of water of 300,000 cubic feet per minute, into which was poured the sewage of Chicago, was started in a tortuous course of a small river at Bear Trap Dam and received no dilution on the way, I do not believe it would be absolutely freed of infection by the time it reached New Orleans. There would be a greater reduction though, in the number of typhoid germs present. If the sewage of Chicago was poured into the Mississippi river at St. Paul, it would purify itself to a large degree by the time it got to St. Louis, but I don't think it would be absolutely purified. It would be dangerous to the people taking water at St. Louis, in the sense that the liability of trouble would always exist to my thought. Absolutely speaking I think that such a thing as the purification of a stream of running water into which infection is poured by sewage is a very doubtful proposition. In order to be absolutely safe, I think the water ought to be filtered.

2630 If there were typhoid bacilli in the Missouri river and the water supply of St. Louis was taken from the Missouri river only, I should advise filtration or some treatment of that water. If there were typhoid bacilli in the waters of the Mississippi and Missouri and the water supply of St. Louis were taken from those two streams without the intermixture of the

Illinois river water, in my judgment it still ought to be filtered. I do not have any idea of the average proportion of Illinois river water passing the intake. I don't think that I would express any figure off-hand. I should think it would be very likely in the vicinity of one-twentieth of the entire body of water that passes the intake.

2631 If I were providing a filter against Missouri river water only I would not make it larger and more elaborate because of its present condition of infection. The same with reference to the Mississippi river water and with reference to the Mississippi and Missouri river water combined, without the Illinois river water.

Q. Would you make it larger and more expensive in its construction if the Illinois river were so included, at the intake at St. Louis?

A. The way that would probably come about in practice is that there would be no very marked difference in the size of the first installation; but the reserve portion of the first installation would serve for a shorter period of years, due to the presence of the Illinois river water and its pollution, than would be the case without that water.

2632 As a general proposition if you are going to manage a filter you ought to have pretty good men to do it and you ought to do it the best you know how, having regard to the health of the people who are to drink the water, but ordinarily a water that can be easily handled by filtration and where the possibility of a slight deterioration in the quality is not a serious matter, it is very seldom in practice that the expense of the organization would be so great. The proper filtration of southern and western waters depends very much upon the skill with which the coagulant is adjusted. The adding of a coagulant is necessary for the water supply of this city at the St. Louis intake, or the Missouri river. There is required some skill and judgment in the man who manipulates the coagulant.

2633 It would require much more skill and judgment to add the coagulant to the filtration of the combined waters of the Mississippi and Missouri and would require still more skill to filter the waters of the three rivers combined. The additional expense would be for the payment of the increased amount to the men who had sense enough to do it and to the members of the staff who would take the responsibility in detail during the 24 hours of each day and each day of the week and each week of the year. I endorsed a project for St. Louis involving mechanical filters following sedimentation of the river water and then coagulation and supplementary subsidence and that this mechanical filtration should be by gravity.

CROSS-EXAMINATION by Mr. Todd:

2634 There should be more experienced and more able men operating the filters here in St. Louis, should the Illinois river containing its infection, become a factor. If twenty men were required to handle the filters I suppose somewhere from four to six would require extra skill. I hardly think that the man at the head of the plant would have to be as skillful and intelligent to operate that plant for the filtration of the waters of the Mississippi and Missouri, as he would have to be if the Illinois river water was added.

2635 The cost of securing a man to operate such a plant would be between the limits of $2,500 and $5,000 a year. I do not know of any man who operates a filter such as would be operated here, in filtering the waters of the Illinois, Mississippi and Missouri, nor of any conditions that would be exactly parallel.

2637 It would cost several thousand dollars a year additional in the management of the plant, if the waters of the Illinois were to be filtered in connection with the waters of the Mississippi and Missouri. The entire additional expense of operating the plant if the waters of the Illinois were filtered would be from twenty to twenty-five thousand dollars. I could not tell you accurately what per cent of the waters passing the intake consist of Illinois water.

2638 I think there may be some days in the course of a year when the waters of the Mississippi and Missouri are more infectious than the waters from the Illinois.

2639 I think there is some Illinois river water at the intake at all times. I think that the general average for the year would show a smaller percentage of Illinois river water than the Missouri and the Mississippi river water combined in the St. Louis intake.

2640 I can conceive of times when the sewage discharges of Kansas City would be a great menace to the public health of St. Louis. If there should be an epidemic in Kansas City, to a certain degree it would be a menace to the water supply of St. Louis. Under average conditions it would take in the neighborhood of a week for the sewage to come from Kansas City to St. Louis. Assuming that in Kansas City there should be an epidemic of typhoid fever and the filter system such as I would construct for the filtration of the Missouri and Mississippi waters, was operated by a less skillful crew than would be established there when the combined waters of the Illinois and Mississippi waters would be filtered, I should hope the filters would be a protection to the public health of St. Louis; under those conditions so operated, I think they would.

Q. Then if the crew that you have mentioned would be able to compete with the epidemic at Kansas City within seven days' journey from the waterworks of St. Louis, why couldn't that same crew protect the city water supply when filtering the waters of the Illinois?

2641 A. It is possible that they might, but there would be the added danger from the Illinois river water in that is intermittently flushing out large accumulations of sediment making the water here much more dangerous than it would in connection with the Kansas City epidemic. When I look into the future I have no pessimistic views about the growth of Kansas City. With its near proximity to St. Louis in point of time and the possibilities of it getting a typhoid contagion, as a general proposition Kansas City is a danger and menace, present and impending to the water supply of St. Louis. I do not consider that the water in the Missouri river at the present time is a fairly safe water.

2642 With the treatment that it receives from the water system existing in St. Louis I should not pronounce it as a safe and usable water in absolute terms, but practically speaking, and based on the experience from 1895 to 1899 I would say that it would be reasonably safe. Practically speaking I consider a filter plant such as we have talked about, absolutely safe, but there is no such thing as an absolute germ-proof filter on a large scale.

2643 The waters of the Missouri, with the typhoid conditions existing from 1893 to 1899 along the watershed of that river, would not be absolutely safe water, after having been treated in the Chain of Rocks settling basins, but I think it would be a reasonably good water. I would consider the waters of the Missouri, after that period so treated, as reasonably safe. Assuming that I was sanitary engineer of St. Louis and they were about to adopt a plant like the one at present in operation and conditions existed along the Missouri river such as I am acquainted with, and the water supply was to be taken from the Missouri river, I should probably recommend that they adopt filtration in connection with it. Assuming the same conditions with the water being taken from the Missouri and Mississippi, excluding the Illinois, prior to 1899, I should still think it would be a reasonably safe water.

2644 Assuming that the water supply came from the Missouri, Mississippi and Illinois rivers, excluding the Chicago sewage, I should still think the water would be safe and usable with the sedimentation which takes place. I think that the sewage poured into the Illinois & Michigan canal prior to 1899 contained infection in a considerable proportion but a large proportion of the infection remained undelivered in the Chicago river. The contents of the Chicago river pumped into the Illinois and Michigan canal were in such a state of advanced decomposition that the proportion of typhoid fever germs originally present in that liquid was comparatively small. The sewage pumped into the Illinois and Michigan canal and then into the Des Plaines river was not absolutely free from infectious germs dangerous to St. Louis, but measured by the infection from 1895 to 1899 at the Chain of Rocks and taking it in connection with the infection coming from the Missouri, Mississippi and Illinois, all these together resulted in a polluted water at the intake tower, but which degree of pollution was not such but that the sedimentation protected the citizens of St. Louis from any serious trouble from typhoid.

2645 If in the watershed of the Illinois, Mississippi and Missouri rivers for 1897, exclusive of Chicago, there were 374 deaths from typhoid fever and as high as 148 in Minneapolis, in its raw condition the water supply of St. Louis was menaced to a certain degree. It was not absolutely free from infection and the liability of infection, but that degree of infection was not such but that the sedimentation which the city waterworks provided could protect reasonably the water consumers of St. Louis. Assuming that the typhoid bacilli discharged from 3740 cases during an average period of fourteen

2646 days was dumped into the watershed of the Mississippi river above its intake, it would pollute the waters of the Mississippi somewhat no doubt; it would be bound to. As to how long it would take that water thus polluted, placed in a sediment basin, to become pure, safe and usable, I don't think any one can answer specifically but it would be a very much longer period than almost any one would be inclined to think, for sedimentation basins holding thirty days' supply are not able uniformly to protect water consumers in such instances where the waters entering such basins are sewage polluted and infected.

2647 The water remains in the settling basins of St. Louis between two and three days. During that time the water is never in a perfectly quiescent state. If all the typhoid germs we are talking about up the several rivers, continue to live and reach the intake tower, the time they would remain in the settling basins would not be sufficient to eliminate them.

2649 A typhoid germ that got into the sedimentation of the settling basin would live there a good long while in all probability. If the water is slightly typhoid infected it would be liable to accumulate a great many of these germs during the course of six months in the sediment.

2650 With such a wind phenomena as we have had during the last two or three weeks passing over these basins, it would have a tendency to stir at the bottom. Provided the churning action of the wind were to get the sediment in there, the water containing these typhoid organisms would be liable to be carried into the outlet and distributed to the people of the city.

2651 A fair general average of the time the water has to settle in these basins would be a day and a half. A day and a half will do very well as far as sedimentation alone is concerned, and it undoubtedly does eliminate a very large number of typhoid germs. The lakes upon the Illinois river and the back water of the different dams in the river would affect the same result, provided all the conditions were the same. Nature would work the same in the two instances. There is a great deal of elimination from the flowing stream of typhoid germs and other bacteria as the water of the Illinois river passes through those basins, but at the Chain of Rocks the sediment is removed by draining the basins and washing them out.

2652 On the Illinois river, the typhoid germs and other bacteria which leave the flowing water and go to the bottom are subsequently flushed out by conditions which naturally occur on that bed, and are returned to the flowing water and many of them doubtless reach the mouth of the stream. I know that it is so from common sense. When these germs sink to the bottom of the lake and the sewage pollution sinks down with them, I presume there is quite a little chemical action going on at the bottom where these microbes are. The anaerobic bacteria have an effect upon the destruction of the typhoid bacilli under conditions such as would obtain in a septic tank or in the Illinois and Michigan canal, but in the bed of the Illinois river where such septic action does not ordinarily, if ever, obtain, I do not think that they would affect the life very materially of the typhoid fever germ. This back water caused by the dam, if my memory serves me right, raises the water some forty or fifty miles back. When the water is not at flood tide in the Illinois river, the current through these back-water basins gets down to less than half a mile an hour.

2653 During those times, sedimentation can and does take place to a considerable degree and the bacteria of typhoid would go to the bed of the river, if they settled—a great many of them would settle. When these settling basins extend over surrounding country where vegetation and grass are plenty, some of these organisms would get out among the grass and when they got out there, it is possible that a freshet would drive them back into the center of the stream, but I think more of them would not go back than would.

2654 The percentage removal of bacteria on an average in the settling basins of St. Louis would be in the neighborhood of 75 per cent. The water used in summer in St. Louis is somewhat in excess of that used during any other period of the year. During those months, the time of sedimentation in the settling basins would be less. I am acquainted with the conditions that obtain in what is known as Lake Joliet.

2655 The current through Lake Joliet goes down to a fraction of a mile, at times. It gets quite rapid at times—very rapid. I presume several miles per hour. I should think that a current of several miles per hour would remove a considerable portion of the bacteria.

2656 When the sewage of Chicago passing through Lake Joliet when the current was only a mile and a quarter or a mile and a half, there would probably be some considerable removal of those germs rrom the flowing stream. It is possible that part of the germs that entered would be scattered and disseminated over that part of the lake which is not adjacent to the current. After it passes Lake Joliet, the first dam it would reach, the principal of which extends for several miles or more, would aid in the removal of germs at times, when the velocity of flow was small, and such velocities at times do occur in my judgment. I suppose those times would aggregate upwards of half a year. When these back-water pools spread out over the country, overflowing the land, the germs that settle along the shores and on the over-flowed land would be less likely to be disturbed by freshets than those just deposited in the bed of the stream, but I think there are undoubtedly conditions which obtain in these overflowed portions which would enable some of those germs lying in the sediment of the overflowed banks to be returned to the stream.

2657 Those conditions would obtain in regard to all the dams along the Illinois river. There would be at times a sedimentation of removal from the flowing stream. They would become deposited upon the bed and following would come the scouring velocities and pick up and move them on. During those times there would be a dying out among the germs. I should not expect that the current at Lake Peoria would exceed two miles an hour under ordinary high stage conditions. Assuming that the current at Lake Peoria was six-tenths of a mile per hour, that velocity would not make a complete removal. There would be disturbances probably, boats and wind actions and such things, which would make a considerable removal of sediment, but not complete. I do not imagine that there are a great many boats that run up the Illinois river from Peoria. On an average when this water gets to Peoria, after passing the dams above Peoria and the lakes above Peoria, considerable elimination of its pollution and infection is accomplished. I presume ordinarily that this is true, but there are times when I think it is not so.

2660 I have not analyzed the sewage that comes from the glucose factory at Peoria. I know that the volume of sewage that is emptied into the Missouri river from the factories and distilleries at Peoria cannot be a very material one, for in examining the analytical evidence I have been unable to detect that that is a controlling—or I might say, a general or dominating factor, taking this entire proposition of the disposal of the Chicago sewage as it comes down through the Illinois river. I should say that the amount of sewage pollution in the Mississippi river at the Chain of Rocks, considering that water in its raw condition, is such that it would not be thoroughly safe. I would ascertain that fact with reference to the amount of pollution entering the streams above. I think it is very essential for any sanitary engineer or expert to ascertain the amount of pollution entering the streams above and it would be a very reckless proposition for any one to make a definite statement in the absence of such information. A sanitary engineer can ascertain from the water itself whether it is safe and usable or dangerous water, through the assistance of tests made for the presence of intestinal bacteria, which is colon bacillus.

2662 There are observers in Switzerland who made examinations of running streams with positive result showing the presence of typhoid germs in the sediment of Lake Geneva and I think also Lake Zurich.

2663 I consider that it is a very clean-cut demonstrated fact that typhoid germs may, do, and have continued to live in the sediment of running waters. I should say for a month or more, possibly in cases for years. I think that the conditions existing in the moist soil in many rural places in this country where typhoid fever prevails from time to time, are proof that typhoid fever germs in the presence of moisture can live for such a term. If that were not so, then there would be an elimination absolutely, of typhoid fever through the rural districts of this and all other countries. My common knowledge of existing conditions in many country towns satisfies me, beyond all doubt, that those germs have lived for at least a year. In a great many instances, my common knowledge is superior to scientific demonstration.

2665 I think those germs live several years. I will not go into details beyond that. I think unquestionably they live several years. I think I am safe in stating that Prof. Sedgewick holds that a typhoid germ will live three years. I do not recall any one who has exploited that longevity for a typhoid bacillus in any work. I think that a prodigiosus bacillus was found in the Ohio river at Cincinnati on one occasion in the course of over a year's investigation, involving practically daily examinations of the waters of that river.

2666 Some typhoid germs, out of a large number put in water, I have no doubt, will live a year.

Q. If a typhoid germ should be deposited in Lake Itasca, from the excreta of an Indian up in that neighborhood, and that the typhoid germ floating down the Mississippi should enter the intake at New Orleans, and get into the system of a creole, would that creole be likely to take typhoid fever?

A. I think there is a decided possibility in that direction, and if there were enough of those individual instances, of one germ coming down from Lake Itasca to the New Orleans intake, there would surely trouble result to the person drinking that water in its raw condition, and in which were present germs coming from Lake Itasca. ?

RE-DIRECT EXAMINATION by General Crow.

Considerable typhoid fever prevails in the city of Louisville. The water supply for that city is drawn from the river and passes through settling basins holding five or six days' supply and in which sedimentation takes place.

2667 The sewage coming into the Ohio river is almost entirely confined to points at and above Cincinnati, which is distant about 150 miles by river. At times of low flow it would take those germs to pass from Cincinnati to the taps of the citizens of Louisville more than one month. I consider that is a very reliable demonstration that typhoid fever germs are not absolutely removed from sewage polluted waters in which that pollution takes place, one month before the water is used. At Covington, Ky., the source of the water supply is the Ohio. There are provided sedimentation basins holding approximately thirty days' supply. It has been found that year after year the citizens of Covington using the Ohio river water coming from those basins are not protected from typhoid fever. I consider that there is no room for doubt but that a portion of the pollution existing in the Ohio river at Cincinnati is due to the sewage coming from cities and towns located in Allegheny County, Pa., between 450 and 500 miles away. I will further say that in my judgment were all sewage pollution of the Ohio river and its tributaries between Pittsburg and Cincinnati eliminated, I consider that the Pittsburg sewage would unquestionably make its influence felt in the hygienic character of the river water at Cincinnati (a distance of between 450 and 500 miles.)

2668 (Witness reads from report of the Chief of Engineers of the United States army in regard to the Illinois river, as follows):

"Channels dredged twenty years ago are but little deteriorated, and it is surprising to find that there has been no deterioration in depth in the pools created by the Henry and Copperas creek dams after from fifteen to twenty-eight years' use."

"The dams (meaning in the Illinois river) have no appreciable effect above mid-stage of the river when currents are the strongest, so that all lighter sediment is swept away as well now as before constructing the dams. That there has been no appreciable change felt in the pools of the Illinois river is a fact that has been so often remarked upon by steamboat men and persons interested in the use of the river since the construction of the first dam at Henry, thirty years ago."

JUDGE JOHNS: I move to strike out portions of the answer which are read from reports.

In my judgment, no great amount of sediment accumulates and remains upon the bed of the stream of the Illinois river for any great length of time.

2669 RE-CROSS EXAMINATION by Judge Johns:

(Witness is examined as to the towns on the Ohio river near Louisville and Cincinnati, and the tributaries of that river entering said river between those points.)

2671 If there was constant accumulation and no scouring out of material that might be deposited on the bed of the Illinois or any other river, the result would be that there would not be any bed there.

WILLIAM H. GETZ, recalled and examined in chief by General Crow:

The table I have here is the same one I presented before, showing the percentage of mixtures of the Mississippi and Missouri rivers at the intake of the St. Louis waterworks. I have re-checked all the calculations and think there is no reason to doubt that that table is correct now as made from examinations and analyses of the water. The difference of amounts of total solids in the Mississippi river and in the Missouri river, at the points where these samples are taken, is found, and also the difference between the total solids at the intake and those at Hartford on the Mississippi river. In this manner the per cent of Mississippi river water is obtained.

The percentage of Missouri river water for instance would be the total difference divided into the difference between the intake and Hartford. (Witness states method of making the calculation of percentages from the table.)

(Table introduced in evidence.)

2679 (Section 2 of table shows calculations based upon daily estimation of total solids.)

2688 HIRAM R. MILLS, examined in chief by Attorney General Crow:

Am physician and reside at Soldiers' Home, Grand Rapids, Mich. Have been practicing medicine 35 years. Resided nearly all the time at Port Huron, Michigan. Left Port Huron on the 25th of April, 1903. Was practicing physician in Port Huron in 1889, '90, '91, '92. Port Huron is on the St. Clair river and the Black river divides Port Huron into two parts and empties into the St. Clair river. There is not a great deal of difference as to the size of the town on either side of the St. Clair river.

2689 The present population of Port Huron is about 21,000. In 1890, '91, '92 it was probably 15,000 or 16,000. A large portion of Port Huron was sewered in 1890, '91, '92 on both sides of the river. The natural drainage for the greater part of the town is into Black river. There has been typhoid fever there off and on every year since I have been there, more or less. I have been there 33 years in December next. In 1891 there were four cases I looked up.

2690 They were under my personal knowledge. There were 4 in 1890 and 4 in 1891. The sewers of Port Huron empty into the Black river almost entirely. They have been emptying in there for a long time.

2691 The river was dredged from the mouth of Black river to the Fiber works in 1891, '92.

CROSS-EXAMINATION by Judge Johns:

There was a board of health in 1891 and '92 but it was not in very active running order. They did not have any statistics of deaths and causes of deaths at that time. The deaths and births were collected by the supervisors twice a year. A record was kept, but I do not know what became of them. As a matter of fact I suppose they were kept—I know that was the law. They had blanks furnished by the State and there was some disposition made of those blanks. There ought to be a copy in the County Clerk's office.

2692 The first case in 1890 was that of Otis Scott, corner Broad and Ontario streets. I attended him personally and he lived. I understood that the house at the time was connected with the sewers but I could not say positively that it was. I told the nurse what to do with the dejecta. She was to use disinfectants and put it into the closet. I think their closet was connected with the sewer. I ordered that before it was put into the sewer it should be disinfected. I told them to use carbolic acid or copperas and sometimes to put in boiling hot water.

2693 The second one was Mrs. Bunce, on Lepear avenue, near 9th st. That was in October, 1890. There was a sewer on Lepear avenue, but I do not know whether their house was connected or not. I always give instructions for the disinfecting of the dejecta. I could not say positively whether the dejecta went into the sewer or not. The next in 1890 was Fred Gooding, Ontario street, near Pine Grove ave. I think that house was connected with the sewer. I am not sure about that either.

2694 I always gave orders to have the dejecta disinfected. I do not know whether it was or not in that case. I could not say positively whether the dejecta from that patient—whether disinfected or not—went into the river.

The next in '90 was Massmore on Lepear ave. That was connected with the sewer. I gave the usual orders to have the dejecta disinfected. I suppose it was done but I don't know. I don't know whether the dejecta—whether disinfected or not—went into the river, but I suppose it did. In 1891 was Mrs. John Folkers, 1209 Miller st. There was no sewer on that street for that house.

2694 The dejecta was thrown into the closet and the closet drained into a little stream there—Indian creek, or the stream that ran down into Indian creek through the
2695 clay. It was one of those surface vaults that might be washed out by flood or something of that kind. At any time there was a heavy rain, there would be a certain amount of sewage from this vault which would go into Indian creek and that went into Black river. I gave the usual orders to have the sewage disinfected but do not think it was done because it was that class of people that would not be apt to do it if you did tell them, while I have no positive knowledge in regard to it.

2696 I have no knowledge positively as to whether the dejecta of that patient—disinfected or not—went into the vault or outhouse; that is a surmise.

In October '91 is another of the same family, living right on the bank of the Black river. This house was not connected with the sewer. The outhouse was practically on the dock over the edge of the river. I gave orders to have the dejecta disinfected but do not know whether it was done. Another in 1891 was John McFadden, Court street. I think it was connected with the sewer in 1891, but I don't know as I never traced
2697 it. Gave the usual orders to have the dejecta disinfected but do not know whether it was done. There was a waterworks in Port Huron in 1890 and 1891. The water supply was taken from the St. Clair river above the mouth of Black river. I think all of these cases in 1890 received their water supply in the houses from the public waterworks of Port Huron. The water of Port Huron was not filtered. It came direct from the St. Clair river.

2698 It is counted one of the best water supplies of the world, but there was contamination there—that is where we got our fever from. The upper part of the city extended quite a distance above the intake pipe and contaminated water was constantly going down from the upper part of the city into the St. Clair river from the cases that occurred along the eastern slope of the city. This man Scott drank the water from the public water supply without filtering it. I am positive of that. I attribute this case of typhoid fever to the contamination of the water supply of Port Huron.

2699 Fred Gooding also received the water from the waterworks. He was the only one in the family having typhoid. I know he drank water from the public supply. I know the Bunce family did not have any well—their water came from the public supply. It is a mere theory that these cases in 1890 and 1891 were attributable to the water supply. It could not be demonstrated. In 1891 the people sick with typhoid who re-

ceived their water from the public water supply were the
Folkers on Miller street.

2700 The Fiber Works are about three-quarters of a mile from
the mouth of Black river. No sewers of the city empty
into the Black river above the Fiber Works. Dredging was
done in the Black river up to the Fiber Works in 1891 and 1892.
These cases were about equally divided on the north and south
side of the city. The waterworks system extended on both sides
of the city.

2701 99 per cent of the people in Port Huron or at least 90
per cent, use the public water supply. The dredging was
started in 1891 in May, June or July, and there was some dredg-
ing done in 1892, probably the first part of the summer.

2702 This dredged material was taken and dumped over the
shallow places, over the tunnel, or in the deep places,
where the tunnel came near breaking through and that would
be probably two-thirds of the way across from the American
side, along the line of the tunnel under the St. Clair river.

2703 It would look as if the major part of this dredging matter
was deposited over in Canadian water about 30 miles
above Lake St. Clair. It may be about 35 or 40 miles by river.
St. Clair river is a wide, rapidly flowing stream and St. Clair
lake is, in places, very shallow. In fact, it is a shallow lake.
The current is along the channel in the lake and there is some-
thing of a current there. It broadens out so that the current is
very much reduced after it leaves the canal—it goes through
the ship canal, you know. The ship canal connects the St. Clair
river with the lake up at Star Island. On the south of
2704 the lake, after you go down the St. Clair river to Lake St.
Clair, then through Lake St. Clair, is the Detroit river.
St. Clair lake was dredged to make a channel but not the entire
length. While the current is not so swift as in the St. Clair
river, there is considerable current in Lake St. Clair. The
Detroit river current is also swift. There is an enormous quan-
tity of water that flows down the St. Clair river.

2705 The river is not subject to great floods. It only varies in depth with the wind. It is a straight between Lake Huron and Lake Erie. It is about 65 miles from Port Huron to Detroit by river. The speed of the current in St. Clair river varies. At the foot of the lake, it is about six miles an hour and as you get down, it is probably about 3 miles an hour in the lake.

2706 The speed of the current of the Detroit river is not as strong and rapid as that of the St. Clair river. There is a considerable agricultural population on both sides of the St. Clair river, having its natural drainage into that river. There are a number of summer resorts and club houses on Lake St. Clair.

2707 It is a great resort—fishing, duck hunting, boating and clubs. Large numbers of people resort there during the fishing and hunting season. The number of resorters at Lake St. Clair and the St. Clair river in the summer would be in the thousands every day. These people might as well have had typhoid fever as anybody else.

2709 CROSS EXAMINATION by Mr. Todd.

2710 Among those 8 people having typhoid fever, two resulted fatally, Mrs. Bunce and Mr. McFadden.

2711 Most of the nurses were just their own people. For instance, Mrs. Bunce was attended by her daughter. I left directions with the nurses in all these cases for the disinfecting of the dejecta and how to attend the patient, and I found that in matters which came directly under my observation, these nurses carried out my instructions and there is no reason to believe they did not. The only thing is, I know that sometimes they get careless about those things, but that is outside of my knowledge. As I said a minute ago, we had our water contaminated from sources above the intake pipe. Exclusive of the sewage of Port Huron, there was what is called McNeil creek which drained quite a territory in that part of the city.

2712 There was nothing outside the city draining into the river.. The theory our medical society has had there always, has been that we had contaminated water or contaminated milk. As to what brought the typhoid fever in this particular locality was not discovered in this particular instance.

2713 It might have come into Port Huron by rail, but there are no cities above Port Huron and it must have come just from the town itself—contamination of the water there.

RE-DIRECT-EXAMINATION by General Crow.

Am not an expert on stream flows. What I said about the rapidity of the current of Lake St. Clair and St. Clair river is guess-work. Typhoid fever has existed in Port Huron for 33 years to my knowledge, that being the time I was there. The disinfectants that are applied to stools of typhoid patients do not always destroy all the typhoid bacilli entirely. If the disinfectants were used in the manner in which I prescribed them to be used, it did kill them—it ought to destroy the germs. I do not know that it was used in that method. My experience as a physician leads me to believe that they did it with a great deal of carelessness.

2715 CHARLES B. STOCKWELL, examined in chief by General Crow.

Am physician and surgeon. Reside at Port Huron, Michigan, have lived there 51 years and practiced medicine 23 years. Was practicing in Port Huron in 1892. There was typhoid fever cases in Port Huron that year. From personal knowledge I have record of three, in February, March and April—one case extended into May. In one case I know there was direct connection with the river by private sewer and in another there was connection through one of the sewers which emptied near the waterworks. In another case, the house was located on the border of Indian creek which emptied into the Black river—whether there was a sewer there or not, I cannot tell.

CROSS EXAMINATION by Judge Johns.

2716 This case in which the sewage went directly into the Black river by private sewer was attended by me personally. The sewage was not disinfected that I remember. I did not give instructions to have it disinfected. That was my practice or custom. The case having indirectly a connection by

ABSTRACT TABLE NO. 1.
